Abstract

Aim

We have limited understanding of which risk factors contribute to increased readmission rates amongst people discharged from hospital with diabetes. We aim to complete the first review of its kind, to identify, in a systematic way, known risk factors for hospital readmission amongst people with diabetes, in order to better understand this costly complication.

Method

The review was prospectively registered in the PROSPERO database. Risk factors were identified through systematic review of literature in PubMed, EMBASE & SCOPUS databases, performed independently by two authors prior to data extraction, with quality assessment and semi-quantitative synthesis according to PRISMA guidelines.

Results

Eighty-three studies were selected for inclusion, predominantly from the United States, and utilising retrospective analysis of local or regional data sets. 76 distinct statistically significant risk factors were identified across 48 studies. The most commonly identified risk factors were; co-morbidity burden, age, race and insurance type. Few studies conducted power calculations; unstandardized effect sizes were calculated for the majority of statistically significant risk factors.

Conclusion

This review is important in assessing the current state of the literature and in supporting development of interventions to reduce readmission risk. Furthermore, it provides an important foundation for development of rigorous, pre-specified risk prediction models.

Key Words:

Diabetes, Inpatient Care, Readmission, Diabetes Complications

1. Introduction

People admitted to hospital have higher rates of diabetes than the general population. In the United Kingdom, 17% of inpatients have a diagnosis of diabetes mellitus [1]. Irrespective of the initial reason for admission, inpatients with diabetes act as a distinct cohort of patients with shared risk factors for adverse events [2]. People with diabetes are at a significantly increased risk of readmission following discharge [3, 4]. Hospital readmissions rates are a psychological and physical burden to patients, and a financial burden on healthcare systems [5]. Despite the importance of readmission amongst people with diabetes, there has been limited research in this area [6]. Specifically, no published studies have attempted to identify, in a systematic way, risk factors relating to readmission for this cohort of patients. There have been attempts to develop and validate risk prediction tools for the readmission of patients with diabetes. Such risk prediction tools report moderate predictive abilities [7, 8], and do not report using the existing research literature to rigorously pre-specify candidate variables.

Understanding risk factors relevant to patients discharged from hospital with diabetes is important to patients, carers, healthcare practitioners and researchers. It supports the delivery and development of individualised medicine, based on each patient's underlying risks; supports our understanding of regional variations in readmission risk, and supports development of evidence based interventions targeted at reducing readmission risks. Interestingly, the paucity of research in this area, for diabetes, is in direct contrast to other medical conditions, such as heart failure [9].

This study therefore aims to identify, systematically, known risk factors for readmission to hospital, among people with diabetes. The intention of the study is to cast a 'broad net', ascertaining all known risk factors, irrespective of whether identified for a specific subset of patients (such as emergency admissions only) or generalised populations of all inpatients with diabetes.

This research will be essential to the planning of future diabetes services, at both an inpatient and community level. It will provide potential targets for improving care, reducing readmission and reducing costs. Identifying a comprehensive list of literature-derived risk factors further facilitates the development of robust pre-specified risk prediction tools. Effective risk prediction models will enable scarce resources to be targeted to patients with the greatest need. Overall, it is hoped that a better understanding of risk factors for people with diabetes will enable the development of discharge planning that is more effective, better patient education interventions, improved risk stratification tools and more targeted interventions.

2. Methods

The systematic review was conducted according to the PRISMA standards[10]. The study protocol was published in advance on the PROSPERO database (Registration Number CRD42017073773).

2.1 Search Strategy

A literature search was performed using PubMed, EMBASE & SCOPUS databases. The search terms selected were “diabetes” AND “readmission.” The search strategy included papers published between August 2006 and August 2018; this wide date range was to ensure that the extracted studies represented current clinical care practices, given historically elongated lengths of stay and differing discharge practices. All study designs were included, with studies limited to English language articles. Due to differing obstetric and paediatric care practices, articles were restricted to adult, non-obstetric patient cohorts. Hand searching of references was performed to identify additional studies for inclusion.

2.2 Study Selection

An initial review of all studies, identified by the literature search, was completed by two authors. Abstracts and titles were reviewed; those papers, not including information regarding risk factors for readmission to hospital in people with diabetes, were removed from the selected studies. Any discrepancies in article selection would be resolved by discussion, involving a third author. All studies selected after the initial screening were reviewed as full text articles, with exclusion of those that did not identify risk factors for readmission, did not consider diabetes, or solely considered diabetes as a risk factor for another condition.

2.3 Data Extraction

Data were extracted to a pre-piloted data collection form. The pro-forma collected information based on the 5 C’s (Category, Context, Correctness, Contribution and Clarity), as suggested by the engineering and computing research community and therefore highly relevant to research articles considering extraction of data from clinical information systems [11]. Additional information collected included: the country within which the study was conducted; whether the study was collected at a local, regional or national level; the extent of inpatient data sources, compared to community or social care data sources; the subset of patients with diabetes included in the study; risk factors that were found to be statistically significantly associated with readmission, alongside risk factors that were identified, but not tested for statistical assessment. Data were collected on the definitions of readmission used by different authors, in particular the time periods elapsed between admission and discharge, alongside an evaluation of approaches used to assess effect sizes of the risk factors identified.

2.4 Quality Assessment

Quality assessment for each of the selected papers was performed against pre-determined standards. These included an assessment of sample size, evidence to justify the sample size, appropriateness of any statistical tests applied, a clear description of study recruitment and assessment, with a final overall narrative assessment of each study’s quality. The aim of this paper is to assess the state of the literature regarding currently understood risk factors for readmission of people with diabetes, and thus no studies were excluded based on low study quality; rather a description is provided within the results section.

2.5 Data Synthesis

The diversity of definitions of readmission used in the research literature, alongside diverse subsets of people with diabetes in different studies, precludes any attempt at meta-analysis. Rather a narrative summary of risk factors identified was extracted, with subsequent thematic grouping of the risk factors as described below.

2.6 Patient Involvement in Research

This research topic was identified as an area of priority for people with diabetes. This was both through the Diabetes Voices Programme [12], operated by Diabetes UK, and individual patient representatives who were identified through NIHR People in Research [13] and reimbursed for their time contribution.

3. Results

3.1 Search Results

The database search strategy identified 1451 articles, with an additional 10 articles identified through manual reference searching. Following abstract-based screening, a total of 122 articles were included for full text extraction and review. Forty articles were excluded following full text review, with 82 studies remaining for full analysis. The results of the search strategy are shown in figure 1.

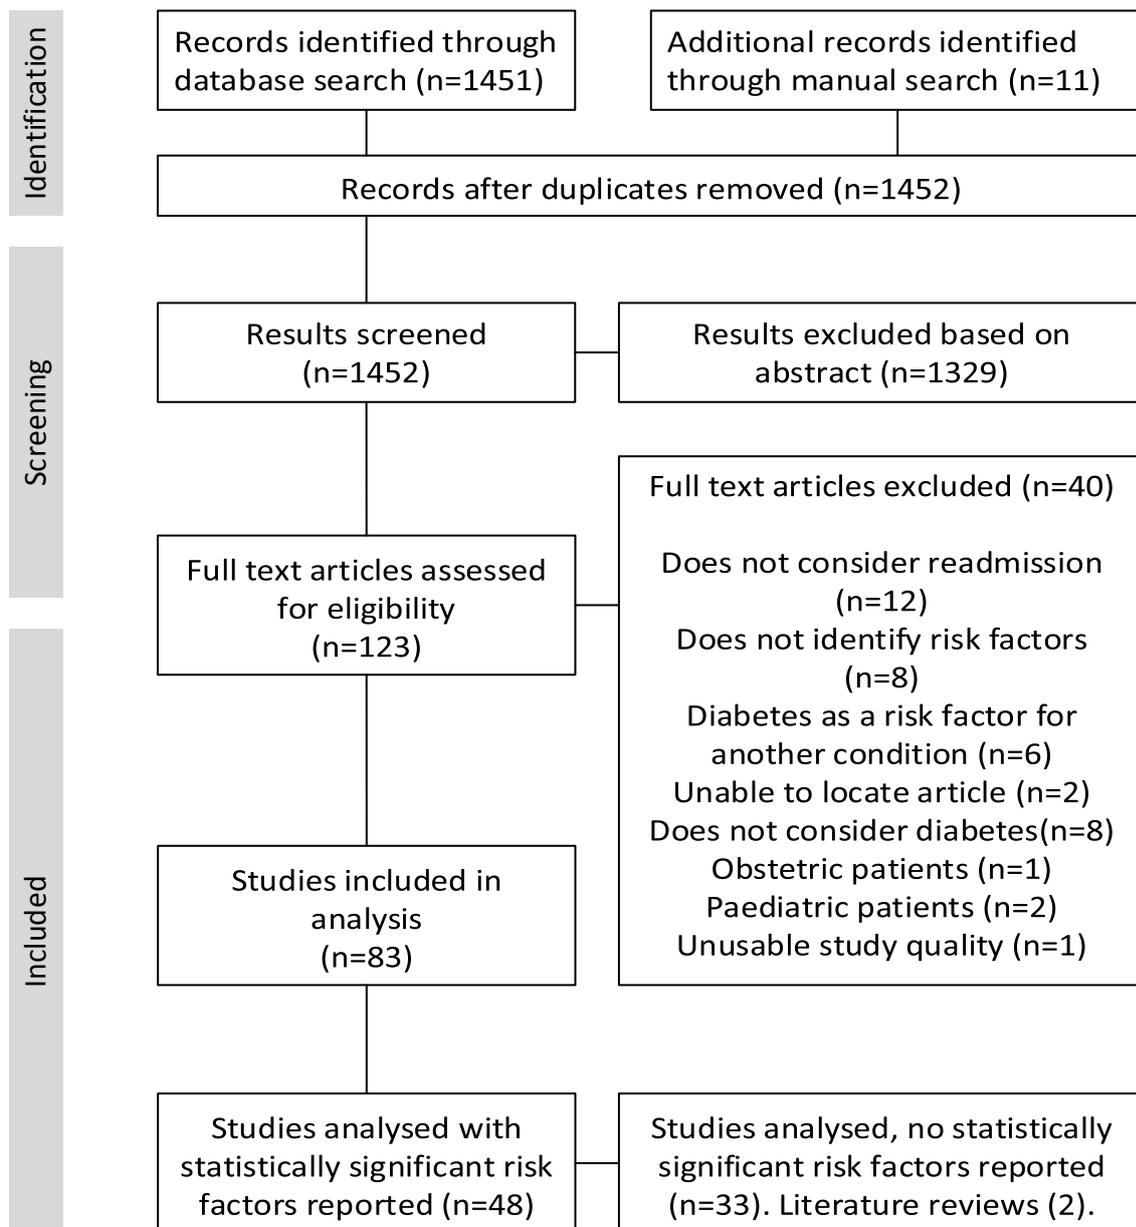

Figure 1: Flow diagram of study selection

3.2 Study Characteristics

From the 83 studies identified, 70 (84%) adopted a retrospective database study design, 2 articles described non-randomised controlled studies, with a single randomised controlled trial. There were 2 prospective pilot studies, 3 prospective cohort studies, 2 case control study, one qualitative study, one systematic review and one narrative review.

The majority of studies were based on patient data from the United States of America (55 studies – 66%), with 9 studies (11%) utilising patient data from the United Kingdom. The remaining studies were conducted based on patient data from Denmark, Australia, Taiwan, Canada, China, Brazil, Italy, Israel, Japan, Saudi Arabia and Spain. One study did not clearly describe the country of origin of the patient population studied.

Studies were predominantly conducted utilising data from a single centre (35 studies, 42%), with 18 studies (22%) utilising data from multiple centres within a single region, and 26 studies using data from a national database (32%). The study setting was unclear in two studies, and not applicable to the review articles. Studies predominantly used inpatient electronic health record sources (68 studies, 83%), with 5 studies (6%) utilising patient data from primary care or community sources and 9 studies (11%) using a combination of both community and inpatient data sources.

Forty-eight studies identified statistically significant risk factors for readmission. The characteristics of these studies are listed in Table 1&2, 20 studies identified risk factors in generalised populations of patients with diabetes (Table 1) and 28 studies identified risk factors for specific sub-populations of patients with diabetes (Table 2). In total, 506 statistically significant risk factors were identified across all analysed studies, including duplicates, with a mean average of 6.10 statistically significant risk factors identified per study. When duplicates were removed, we collated 76 distinct risk factors for readmission of people with diabetes from the published literature. A full breakdown of risk factors identified during the data collection process is shown in Table 3. The risk factors are divided into whether they were identified for only a specific subpopulation of people with diabetes, or whether they were identified for generalised diabetes populations.

From the studies identifying statistically significant risk factors there were 12 different definitions of readmission used, ranging from 7-days from index hospital discharge, to 5-years from index hospital discharge. The studies in Table 1 and 2 are ordered by this readmission definition.

In addition to those risk factors found to have a statistically significant impact on research, 19 papers identified risk factors that had an impact on outcomes but did not reach statistical significance. This represented a total of 39 risk factors for readmission, 11 of which were unique and not identified in the list of risk factors recognised as statistically significant. These are outlined in Table 4. None of the 19 studies, identifying these non-significant risk factors, reported a power calculation to ensure they had a sufficient patient population to identify significance, if present.

3.3 Study Quality

Studies typically had large sample sizes of patients, with a median average sample size of 6603 patients. Seven studies, however, included less than 100 participants [14-20]. All quantitative studies described the statistical approach taken to analysing data, and these were appropriate to the study design. One quantitative study did not complete any statistical significance testing [21]. Generally, there was a failure to pre-specify which risk factors would be assessed as primary or secondary outcomes measures, and thus any justification for the selection of these studies. Of central importance, only 2 studies (4%) described or provided the results of a power calculation, in order to justify the sample sizes used and relevance of the subsequent statistical tests. One study was unclear regarding their description of patient recruitment and subsequent patient characteristics [22].

From the studies that identified statistically significant risk factors, 95% reported an effect size related to the risk factors identified. All effect sizes were reported using non-standardised statistical methods (typically Odds Ratio or Hazard Ratio), rather than standardised effect size measures (such as Cohen's D or Phi).

There was a single qualitative study [14], which was rigorously performed with semi-structured interviews and thematic analysis. It, however, was restricted to a single (urban) centre. Twenty-three studies were conducted only in a single centre, potentially restricting their generalisability.

Table 4: Additional risk factors with non-significant impact on readmission rate

4. Discussion

Reducing readmission risk following hospital discharge, is a key priority for patients and policy makers across healthcare systems. People with diabetes are at an increased risk of hospital readmission. This article represents the first review of its kind, aiming to identify, in a systematic way, risk factors for readmission to hospital, amongst both generalised and specific populations of people with diabetes. A total of 76 distinct statistically significant risk factors were identified, with the most commonly identified being co-morbidities (16 studies), age (13 studies), race (10 studies), insurance type (8 studies), sex (7 studies). A requirement for insulin was a widely reported risk factor either before admission, during admission or subsequent to discharge.

The research remains at a relatively early stage of maturity, with the majority of studies representing retrospective reviews of local or regional datasets. The research is dominated by studies from the USA, which itself has a unique insurance-based approach to healthcare, and thus may not be representative of readmission patterns in other countries.

There were only two review articles that considered risk factors for readmission, one study was for a particularly specific subset of patients following cardiac surgery [71], and the other a narrative review article considering generalised diabetes readmission and prevention opportunities [6]. One study took a qualitative approach to data collection [14]. Given the nature of diabetes, as a disease of self-management, it is important that we gain a greater qualitative understanding of factors affecting readmission. The absence of qualitative studies may explain the relative paucity of psychological and patient-educational factors in the list of statistically significant risk factors extracted into Table 2.

The methodological and statistical approaches, to identifying risk factors, are also at an early stage of maturity. Whilst studies have relatively large sample sizes, there was rarely any attempt to identify the required sample sizes to meet significance testing through appropriate power calculations. This may explain the relatively low average number of statistically significant risk factors identified per study. It is a particular concern that, this approach to statistical planning for studies may mean that a number of risk factors, which could be statistically significant, were an appropriate sample size was selected, could have been missed. Conversely, the significant risk factors identified in Table 1 & 2 include those based on univariate comparisons, and it is important to note that univariate significance may disappear after adjustment for confounders in multivariable modelling. We have included risk factors identified through univariate comparison in order to provide a comprehensive overview of the current literature.

The underlying variation in the patient populations described (both in the generalised patient populations and specific patient populations), alongside significant variation in the definition of readmission and use of unstandardized effect size statistical tools, precludes a meaningful quantitative meta-analysis of the effect sizes described, in order to create a “hierarchy” of risk factors, or to assess the consistency across studies identifying the same risk factors. The further comprehensive, quantitative evaluation of risk factors, in properly powered multi-centre studies will be essential to better understanding and modifying the risk factors, most relevant to patients diagnosed from hospital with diabetes.

The risk factors acknowledged in this review, demonstrate a truly diverse set of factors that significantly contribute to readmission risks in patients with diabetes. Interestingly, relatively little overlap exists between studies, with 29 risk factors (38%) being identified in just one study. Risk factors are relatively evenly distributed across the demographic, socio-economic, lifestyle, patient medical, medication related and pathology result categories described above. Forty-one percent of risk factors (31 risk factors) were identified in both studies examining a subset of populations with diabetes, and those identifying risk factors for generalised populations of patients with diabetes. This overlap potentially raises the argument that people with diabetes can be treated as a distinct population within the inpatient setting.

This study has a number of strengths including pre-registration in PROSPERO; a clearly defined, two-person search across three databases; assessment of study quality; semi-quantitative data synthesis; and patient and public involvement demonstrating the research question as a priority for patients. There are, however, a number of limitations that should be considered, including the fact that the study only considers English Language papers. There is also a potential limitation in the grouping of risk factors identified as statistically significant in Table 2; for example, mental health diagnoses have been grouped separately, whilst some might argue they could be considered together. The groupings have, however,

been decided across the research team, and individualised references provided to support future researchers.

This study identifies a number of key research priorities to better support patients at discharge from hospital with diabetes. Many of the studies reported mortality outcomes following discharge alongside readmission outcomes, and it will be important to assess the extent to which the research literature has considered mortality outcomes, given a lack of systematic review in this area. Similarly, the inability to perform a quantitative meta-analysis of effect sizes, related to individual risk factors identified, demonstrates an important gap in the research literature.

Taken together, the literature demonstrates that risk factors can, and have been identified for people with diabetes, being readmitted to hospital. This is a valuable resource to patients, clinicians and academics looking to improve the process of inpatient discharge from hospital. There is a clear need for statistically rigorous studies, which incorporate data from both inpatient, community and qualitative sources to understand further these diverse risk factors, matched to meaningful effect sizes, to be developed. Such research would act as the foundation for both cohorting at risk patient populations and introducing targeted personalised interventions, in order to improve the quality of care provided for people with diabetes.
