POINT-TO-LINE POLYMERS AND ORTHOGONAL WHITTAKER FUNCTIONS

ELIA BISI AND NIKOS ZYGOURAS

Abstract. We study a one dimensional directed polymer model in an inverse-gamma random environment, known as the log-gamma polymer, in three different geometries: point-to-line, point-to-half-line and when the polymer is restricted to a half-space with end point lying free on the corresponding half-line. Via the use of A.N.Kirillov’s geometric Robinson-Schensted-Knuth correspondence, we compute the Laplace transform of the partition functions in the above geometries in terms of orthogonal Whittaker functions, thus obtaining new connections between the ubiquitous class of Whittaker functions and exactly solvable probabilistic models. In the case of the first two geometries we also provide multiple contour integral formulae for the corresponding Laplace transforms. Passing to the zero-temperature limit, we obtain new formulae for the corresponding last passage percolation problems with exponential weights.

1. Introduction

Recent efforts in understanding the structure that underlies the Kardar-Parisi-Zhang universality class has led to remarkable connections between probability, combinatorial structures and representation theoretic objects. Some of the highlights include the solvability of the Asymmetric Simple Exclusion Process (ASEP) by Tracy and Widom [TW09a, TW09b] via the method of Bethe Ansatz, the construction of Macdonald Processes by Borodin and Corwin [BC14] and various particle processes ($q$-Totally Asymmetric Simple Exclusion Process, $q$-Totally Asymmetric Zero Range Process etc.) that fall within this scope, the stochastic six-vertex model [BP16], the Brownian, semi-discrete polymer and its relation to the Quantum Toda hamiltonian as established by O’Connell [O12] and the exactly solvable log-gamma directed polymer, which was introduced by Seppäläinen [Sep12] and analyzed in [COSZ14, OSZ14, BCR13, NZ15].

In this article we study further the log-gamma polymer and its structure and we establish new connections to the representation theoretic object known as Whittaker functions, which appear in various different places such as mirror symmetry [Giv97] (see [Lam13] for a review) and quantum integrable systems [KL01] and are of central importance in the theory of automorphic forms [Bum89, Gold06].

The log-gamma polymer is defined as follows: On the lattice $\{(i,j): (i,j) \in \mathbb{N}^2\}$ we consider a family of independent random variables $\{W_{i,j}: (i,j) \in \mathbb{N}^2\}$ distributed as inverse-gamma variables

$$P(W_{i,j} \in dW_{i,j}) = \frac{1}{\Gamma(\gamma_{i,j})} w^{-\gamma_{i,j}} e^{-1/w_{i,j}} \frac{dw_{i,j}}{w_{i,j}}, \quad (i,j) \in \mathbb{N}^2,$$

with $\gamma_{i,j}$ positive parameters. For $(p,q) \in \mathbb{N}^2$ fixed, denote by $\Pi_{p,q}$ the set of all directed, nearest neighbor paths from $(1,1)$ to $(p,q)$, called polymer paths. The log-gamma polymer measure gives to every such path $\pi$ a weight

$$\frac{1}{Z_{p,q}} \prod_{(i,j) \in \pi} W_{i,j},$$

where the normalization

$$Z_{p,q} := \sum_{\pi \in \Pi_{p,q}} \prod_{(i,j) \in \pi} W_{i,j} \quad (1.1)$$

is called the point-to-point partition function of the log-gamma polymer. The characterization point-to-point is due to the fact that only paths that start at a fixed point $(1,1)$ and end at a fixed point $(p,q)$ are considered. The partition function $Z_{p,q}$ can be viewed as a discrete version of the solution to the Stochastic Heat Equation (SHE) in dimension one

$$\partial_t u = \frac{1}{2} \partial_x^2 u + \hat{W}(t,x) u, \quad (1.2)$$

with delta initial condition at zero, where $\hat{W}(t,x)$ is space-time white noise. The transformation $h = \log u$ of the solution to (1.2) leads, then, to the solution of the KPZ equation

$$\partial_t h = \frac{1}{2} \partial_x^2 h + \frac{1}{2} (\partial_x h)^2 + \hat{W}(t,x), \quad (1.2)$$

under the so-called narrow wedge initial condition. See [Sep12] for the introduction of log-gamma polymer, as well as the more general, recent review on random polymers [Com17].
Using ideas from algebraic combinatorics and in particular A.N.Kirillov’s geometric Robinson-Schensted-Knuth correspondence [K01] (see also [NY01] [COSZ14] [OSZ14] were able to determine the Laplace transform of the point-to-point partition function for a log-gamma polymer with parameters $\gamma_{i,j} = \alpha_i + \beta_j$ and make a connection to $GL_n(\mathbb{R})$-Whittaker functions (an earlier connection between the Brownian, semi-discrete polymer and $GL_n(\mathbb{R})$-Whittaker functions appeared in [O12]). In particular, it was established that
\[
\mathbb{E}\left[e^{-rZ_{n,n}}\right] = \frac{1}{\prod_{1 \leq i,j \leq n} \Gamma(\alpha_i + \beta_j)} \int_{\mathbb{R}_+^n} e^{-rx_1^{-1/2}x_n} \Psi_{\alpha,\beta}^{\text{gl}}(x) \prod_{i=1}^n \frac{dx_i}{x_i},
\]

where $x = (x_1, \ldots, x_n)$, $\alpha = (\alpha_1, \ldots, \alpha_n)$, $\beta = (\beta_1, \ldots, \beta_n)$ and $\Psi_{\alpha,\beta}^{\text{gl}}(x)$ are the $GL_n(\mathbb{R})$-Whittaker functions (see section 2.1 for details) [COSZ14]. Furthermore, using the Plancherel theory for $GL_n(\mathbb{R})$-Whittaker functions a contour integral formula was derived for (1.3), which was subsequently turned into a Fredholm determinant in [BCR13] allowing to derive the Tracy-Widom GUE asymptotics.

In this work we consider the directed polymer with inverse gamma disorder but with the end point lying free on a line. In particular, we will consider three different geometries of paths (see also Figure 1 for a graphical representation):

(i) **point-to-line (or flat)**, which we denote $\Pi^{\text{flat}}_n$ and consider to be the set of all directed paths from $(1,1)$ to the line $\{(i,j) : i + j = n + 1\}$. The corresponding partition function is then
\[
Z^{\text{flat}}_n := \sum_{\pi \in \Pi^{\text{flat}}_n} \prod_{(i,j) \in \pi} W_{i,j}.
\]

(ii) **point-to-half-line (or half-flat)**, which we denote $\Pi^{\text{half-flat}}_n$ and consider to be the set of all directed paths from $(1,1)$ to the half-line $\{(i,j) : i + j = n + 1, i \leq j\}$. The corresponding partition function is then
\[
Z^{\text{half-flat}}_n := \sum_{\pi \in \Pi^{\text{half-flat}}_n} \prod_{(i,j) \in \pi} W_{i,j}.
\]

(iii) **restricted point-to-half-line (or restricted half-flat)**, which we denote $\Pi^{\text{r-flat}}_n$ and consider to be the set of all directed paths from $(1,1)$ to the half-space $\{(i,j) : i + j = n + 1, i \leq j\}$ and with paths $\pi \in \Pi^{\text{r-flat}}_n$ restricted to the half-space $\{(i,j) : i \leq j\}$. The corresponding partition function is then
\[
Z^{\text{r-flat}}_n := \sum_{\pi \in \Pi^{\text{r-flat}}_n} \prod_{(i,j) \in \pi} W_{i,j}.
\]

We will compute the Laplace transform of the above partition functions in terms of Whittaker functions corresponding to the orthogonal group $SO_{2n+1}(\mathbb{R})$, which we will denote by $\Psi_{\alpha}^{\text{pgn}}(x)$, with $\alpha = (\alpha_1, \ldots, \alpha_n)$ and $x = (x_1, \ldots, x_n)$ (see Section 2.2 for

‡ Originally named tropical by Kirillov in his article “Introduction to Tropical Combinatorics” [K01].

† Even though Whittaker functions are typically associated to Lie groups, for notational convenience we will be mostly using mathfrak symbols, $\mathfrak{gl}_n$, $\mathfrak{so}_{2n+1}$ etc., which are normally used for Lie algebras.
Figure 1. Directed paths in $\mathbb{N}^2$ of length $10$ from the point $(1, 1)$ to the line $i + j - 1 = 10$. The three paths, highlighted in red, correspond to three different geometries, as specified. The picture is rotated by $90^\circ$ clockwise w.r.t. the Cartesian coordinate system, to adapt it to the usual matrix/array indexing.

(\textbf{c}) Restricted path

details), as well as $GL_n(\mathbb{R})$-Whittaker functions $\Psi_{\alpha}^{\text{so}_n}(x)$. More precisely, after choosing appropriately the parameters $\gamma_{i,j}$ of the inverse gamma variables, we obtain that

$$E \left[ e^{-rZ_{2n}^{\text{flat}}} \right] = \frac{\sum_{i=1}^{n} (\alpha_i + \beta_i)}{\Gamma_{\alpha,\beta}^{\text{flat}}} \int_{\mathbb{R}_+^n} e^{-rx_1} \Psi_{\alpha}^{\text{so}_2n+1}(x) \Psi_{\beta}^{\text{so}_2n+1}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i},$$

(1.7)

$$E \left[ e^{-rZ_{2n}^{\text{h-flat}}} \right] = \frac{\sum_{i=1}^{n} (\alpha_i + \beta_i)}{\Gamma_{\alpha,\beta}^{\text{h-flat}}} \int_{\mathbb{R}_+^n} e^{-rx_1} \Psi_{\alpha}^{\text{so}_2n+1}(x) \Psi_{\beta}^{\text{so}_2n+1}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}, \quad \text{and}

(1.8)

$$E \left[ e^{-rZ_{2n}^{\text{r-flat}}} \right] = \frac{\sum_{i=1}^{n} \alpha_i}{\Gamma_{\alpha}^{\text{r-flat}}} \int_{\mathbb{R}_+^n} e^{-rx_1} \Psi_{\alpha}^{\text{so}_2n+1}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i},$$

(1.9)

where $\Gamma_{\alpha,\beta}^{\text{flat}}$, $\Gamma_{\alpha,\beta}^{\text{h-flat}}$ and $\Gamma_{\alpha}^{\text{r-flat}}$ are suitable normalization constants. It is interesting to note the structure of these formulae in comparison to formula (1.3) for the point-to-point polymer. Informally, one could say that “opening” each part of the end point’s “wedge” to a (diagonally) flat part corresponds to replacing a $GL_n(\mathbb{R})$-Whittaker function with an $SO_{2n+1}(\mathbb{R})$-Whittaker function. However, a priori there is no obvious reason why this analogy should take place.

Whittaker functions associated to general Lie groups have already appeared in probability in terms of describing the law of Brownian motion on these Lie groups conditioned on certain exponential functionals [BO11], [Ch13]. The latter reference provides also a comprehensive account of various algebraic properties and origins of Whittaker functions. Further extensions in this direction, in both the “Archimedean” and “non-Archimedean” cases have been achieved in [Ch15, Ch16]. In [Nte17] $SO_{2n+1}(\mathbb{R})$-Whittaker functions also emerged in the description of the Markovian dynamics of systems of interacting particles restricted by a soft wall. In our setting, $SO_{2n+1}(\mathbb{R})$-Whittaker functions emerge through a combinatorial analysis of the log-gamma polymer via the geometric Robinson-Schensted-Knuth correspondence. Using the framework and properties of geometric RSK as in [NZ13], we determine the joint law of all point-to-point partition functions with end point on a line or half line. Subsequently, we are able to derive an integral formula for the Laplace transform of the various point-to-line partition functions after expressing them as a sum of the corresponding point-to-point ones. These formulae do not immediately relate to Whittaker functions but
do so after a change of variables and appropriate decompositions of the integrals, thus leading to formulae (1.7), (1.8), (1.9). Even though simple, the alluded change of variables is remarkable in the sense that it precisely couples the structure of orthogonal Whittaker functions with the combinatorial structure of the point-to-line polymers and their Laplace transforms. We should note that we would probably not be able to relate to Whittaker functions, had we aimed to compute functionals of the point-to-line partition other than the Laplace transform. Nevertheless, the Laplace transform is the most relevant functional as it determines the distribution. Once (1.7), (1.8), (1.9) are obtained we go one step further by rewriting the first two of them as contour integrals involving Gamma functions (even though we can also formally write (1.9) as a contour integral, we miss the necessary estimates that would fully justify such a representation). This is done via the use of Plancherel theory for $GL_n$-Whittaker functions and special integral identities of products of $GL_n \times GL_n$ and $GL_n \times SO_{2n+1}$ Whittaker functions due to Bump-Stade [Bum84, Stau02] and Ishii-Stade [IS13], respectively. Such integral identities are important in number theory as they lead to functional equations for $L$-series, facilitating the study of their zeros [Bum89]. Currently, there do not exist such integral identities for products of $GL_n \times SO_{2n}$ and that is why we restrict our presentation to polymers $Z_{2n}$ of even length, even though our combinatorial analysis allows one to write the corresponding formulae (1.7), (1.8), (1.9) for polymers of odd length, as well, in terms of $SO_{2n}(\mathbb{R})$—Whittaker functions.

Calabrese and Le Doussal studied in [CLeD11, CLeD12] the continuum random polymer with flat initial conditions. Via the non-rigorous approach of Bethe ansatz for the Lieb-Liniger model and the replica trick, they exhibited that its Laplace transform can be written in terms of a Fredholm Pfaffian from which the Tracy-Widom GOE asymptotics are derived. In their method they had first to derive a series representation for the half-flat initial condition and then the flat case was deduced from the former via a suitable limit. More recently, [G17] applied the method of Calabrese and Le Doussal and of Thiery and Le Doussal [TLeD14] to study, again at non-rigorous level, the Laplace transform of the log-gamma polymer with end point lying free on a line. Ortmann-Quastel-Remenik [OQR16, OQR17] have made a number of steps in the approach of Calabrese and Le Doussal rigorous in the case of the Asymmetric Exclusion Process (see also the earlier work of Lee [Lee10]). In the half-flat case [OQR16] derived a series formula for the $q$-deformed Laplace transform of the height function. Formal asymptotics on this formula have indicated that the (centered and rescaled) limiting distribution should be given by the one-point marginal distribution of the Airy$_{2\to 1}$ process, which is expressed in terms of a Fredholm determinant. However, a Fredholm structure is not apparent before passing to the limit. In the flat case [OQR17], following [CLeD11, CLeD12], obtained a series formula for the same $q$-deformed Laplace transform of the height function as a limit of the half-flat case. The formula obtained for the flat case does not have an apparent Fredholm structure, either. However, for a different $q$-deformation of the Laplace transform a Fredholm Pfaffian appears, but the pitfall of this new deformation is that it does not determine the distribution of the height function.

Our approach is orthogonal to the methods used in the above works. We do not rely on Bethe ansatz computations but we rather explore the underlying combinatorial structure of the log-gamma polymer. Moreover, we do not derive the flat case as a limit of the half-flat but, instead, we work with the common underlying structure, which allows for a more unified and systematic approach giving access to other geometries, as well. We do not pursue in this work an asymptotic analysis on the law of the partition functions as our primary focus has been the analysis of their combinatorial structure and the links to orthogonal
Whittaker functions. We hope, though, that the method developed here can provide a route to the asymptotic analysis of the log-gamma polymer in the flat and half-flat geometries and this is currently under investigation. This hope is also reinforced by the fact that in the zero temperature case (see the discussion that follows) the formulae that emerge from our approach provide alternative derivations of GOE and Airy$_{2+1}$ statistics [BZ17]. In particular, they offer an alternative route to Sasamoto’s Fredholm determinant formula for GOE [Sa05].

In the zero temperature setting, Baik-Rains [BR01] (see also Ferrari [Fe04] for a continuum, Hammersley last passage percolation model) studied the point-to-line last passage percolation

$$
\tau_{n}^{\text{flat}} := \max_{\pi \in \Pi_{n}^{\text{flat}}} \sum_{(i,j) \in \pi} W_{i,j}
$$

with geometrically distributed weights $W_{i,j}$ via the use of the standard Robinson-Schensted-Knuth correspondence and the observation that

$$
\tau_{n}^{\text{flat}} = \frac{1}{2} \max_{\pi \in \Pi_{n,n}} \sum_{(i,j) \in \pi} W_{s}^{i,j},
$$

(1.10)

where $\Pi_{n,n}$ is the set of directed paths from $(1,1)$ to $(n,n)$ and the matrix $(W_{s}^{i,j} : 1 \leq i, j \leq n)$ is symmetric along the anti-diagonal, i.e. $W_{s}^{n-i+1,n-j+1} = W_{s}^{i,j}$, for all $(i,j)$ with $i+j \leq n+1$. However, in the polymer case (positive temperature) considering a point-to-point directed polymer on a symmetric along the anti-diagonal matrix does not give the point-to-line partition functions, as instead of (1.10) one obtains that

$$
Z_{s}^{n,n} = \sum_{(i,j) : i+j=n+1} (Z_{s}^{i,j})^2,
$$

(1.11)

where $Z_{s}^{n,n}$ denotes the point-to-point partition function on an antisymmetric matrix. Accordingly, our use of the geometric Robinson-Schensted-Knuth correspondence does not go through the route of applying it to antisymmetric matrices.

From our formula (1.7) we can pass to the zero temperature limit by scaling suitably the parameters of the inverse gamma variables and obtain the distribution function of $\tau_{2n}^{\text{flat}}$ for exponentially distributed weights $W_{i,j}$ in terms of (the continuous analogue of) symplectic $Sp_{2n}$–Schur functions $sp_{\mu}()$. In the discrete setting, i.e. for geometric weights with distribution

$$
P(W_{i,j} = k) \propto (y_{1}y_{2n+1-j})^{k}, \quad k = 0, 1, 2, \ldots,
$$

our formula would read as

$$
P(\tau_{2n}^{\text{flat}} \leq u) \propto \sum_{\mu \in \mathbb{Z}_{+}^{2n}, 0 \leq \mu_{n} \leq \cdots \leq \mu_{1} \leq u} sp_{\mu}(y_{1}, \ldots, y_{n}) sp_{\mu}(y_{2n}, \ldots, y_{n+1}).
$$

(1.11)

The analogue of formula (1.11) for exponential weights, established in [4.7], appears to be new and it is worth comparing it to the corresponding formula of Baik-Rains [BR01] for geometrically distributed weights, which is given in terms of a single Schur function as

$$
P(\tau_{2n}^{\text{flat}} \leq u) \propto \sum_{\mu \in \mathbb{Z}_{+}^{2n}, 0 \leq \mu_{2n} \leq \cdots \leq \mu_{1} \leq u} s_{2\mu}(y_{1}, \ldots, y_{2n}).
$$

Formula [4.7] comes from the fact that the zero temperature limit of $SO_{2n+1}$-Whittaker functions are continuum versions of $Sp_{2n}$-Schur functions. This might seem a bit peculiar as one might expect to get the corresponding orthogonal Schur functions in the limit. The reason for this is that $SO_{2n+1}$-Whittaker functions have an integral representation over an analogue of the Gelfand-Tsetlin patterns that correspond to the symplectic group $Sp_{2n}$ (see Definition
Figure 2. Triangular arrays as in (2.1). The arrows refer to formula (2.3): $E_\triangle(z)$ is the sum of all $a/b$ such that there is an arrow pointing from $a$ to $b$ in the diagram.

2.4 and Figure 3B, which is dual to the orthogonal group $SO_{2n+1}$. This is in agreement with the Casselma-Shalika [CS80] formula which describes the (unramified) Whittaker functions of a group $G$ as characters of a finite dimensional representation of the dual group of $G$ (see also [Ch16] for a probabilistic approach): the dual group of $SO_{2n+1}$ is $Sp_{2n}$, while the dual of $GL_n$ is itself, hence $GL_n$-Whittaker functions are the analogue of Schur functions, while $SO_{2n+1}$-Whittaker functions are the analogue of $Sp_{2n}$-Schur functions.

**Organization of the article.** In Section 2 we introduce the Whittaker functions corresponding to $GL_n(\mathbb{R})$ and $SO_{2n+1}(\mathbb{R})$ and record the properties that will be useful for this work. In Section 3 we derive formulae (1.7), (1.8), (1.9) for the Laplace transforms in terms of Whittaker functions and then in terms of contour integrals in the first two cases. In section 4, we pass to the zero temperature limit and obtain formulae for the law of the point-to-line last passage percolation with exponentially distributed waiting times in terms of symplectic and classical Schur functions and also in terms of determinantal/Pfaffian formulae. Finally, in Appendix A we show the equivalence of the parametrization we adapt for Whittaker functions and the parametrization used in number theory.

## 2. Whittaker functions

As we already mentioned, Whittaker functions appear in many different contexts and as a result they have various different ways of definition. In number theory (theory of automorphic forms) they emerge as eigenfunctions of a commuting family of differential operators - the center of the universal enveloping algebra of the associated group - that have certain invariance properties [Gold06]. In that context, Jacquet [J67] introduced what is known as *Jacquet Whittaker function* via a certain integral representation. In a representation theoretic setting, Konstant [Ko78] constructed Whittaker functions as a solution to the quantum Toda lattice. In quantum cohomology and mirror symmetry, Givental [Giv97] viewed Whittaker functions as solutions to a certain integrable system, which turned out to be the quantum Toda lattice to which he constructed integral solutions via mirror symmetry. This approach was extended further for general classical groups by Gerasimov-Lebedev-Oblezin [GLO07, GLO08]. From that quantum cohomology setting further integral representations over geometric crystals have also emerged [Lam13, Ric12]. A nice algebraic summary of various incarnations of Whittaker functions appears in [Lam13] and an account touching upon both algebraic and probabilistic aspects in [Ch13].

Here, we will deal with $GL_n$ and $SO_{2n+1}$-Whittaker functions and the most relevant representation in our context is that of Givental and Gerasimov-Lebedev-Oblezin. In the
following subsections we will recall these integral representations as well as other aspects of Whittaker functions which are important for our purposes.

2.1. \( \mathfrak{gl}_n \)-Whittaker functions. Following Givental [Giv97], see also [GLO07, GLO08], we introduce \( \mathfrak{gl}_n \)-Whittaker functions, as integrals on triangular patterns. Let \( n \geq 1 \), and consider a triangular array of depth \( n \)

\[
\mathbf{z} = (z_{i,j} : 1 \leq i \leq n, \ 1 \leq j \leq i)
\]

(2.1)

with positive entries; examples are given in Figure 2. Whenever the entries are interlaced, that is

\[
z_{i+1,j+1} \leq z_{i,j} \leq z_{i+1,j} \quad \text{for} \quad 1 \leq j \leq i \leq n - 1,
\]

(2.2)

such arrays are known as Gelfand-Tsetlin patterns. Here, we will be working with triangular arrays that do not satisfy the interlacement condition (2.2). We will call such triangular arrays geometric Gelfand-Tsetlin patterns. Even though geometric Gelfand-Tsetlin patterns do not satisfy (2.2), we will impose a potential \( \mathcal{E}^\Delta (\mathbf{z}) \) on them, which encourages interlacement. This potential is (see Figure 2 for a graphical representation)

\[
\mathcal{E}^\Delta (\mathbf{z}) := n - 1 \sum_{i=1}^{n} \sum_{j=1}^{i} \left( \frac{z_{i+1,j+1}}{z_{i,j}} + \frac{z_{i-1,j}}{z_{i+1,j}} \right).
\]

(2.3)

We will call \( i \)-th row of \( \mathbf{z} \) the vector \( (z_{i,1}, \ldots, z_{i,i}) \) of all entries with first index equal to \( i \). The set of geometric Gelfand-Tsetlin patterns of depth \( n \) and with bottom row equal to a vector \( \mathbf{x} \in \mathbb{R}^n \) will be denoted by \( \mathcal{T}_n^\Delta (\mathbf{x}) \). We also define the type, \( \text{type}(\mathbf{z}) \in \mathbb{R}^n_+ \) as the vector whose \( i \)-th component is the ratio between the product of the \( i \)-th row elements of \( \mathbf{z} \) and the product of its \((i-1)\)-th row elements; in other words,

\[
\text{type}(\mathbf{z})_i := \frac{\prod_{j=1}^{i} z_{i,j}}{\prod_{j=1}^{i-1} z_{i-1,j}} \quad \text{for} \quad i = 1, \ldots, n,
\]

where empty products are excluded from the expressions (as we will always suppose from now on). We now define the \( \mathfrak{gl}_n \)-Whittaker functions via an integral representation:

**Definition 2.1.** The \( \mathfrak{gl}_n \)-Whittaker function with parameter \( \alpha \in \mathbb{C}^n \) is given by

\[
\Psi^{\mathfrak{gl}_n}_\alpha (\mathbf{x}) := \int_{\mathcal{T}_n^\Delta (\mathbf{x})} \text{type}(\mathbf{z})^\alpha \exp \left( - \mathcal{E}^\Delta (\mathbf{z}) \right) \prod_{1 \leq i < n, 1 \leq j \leq i} dz_{i,j},
\]

(2.4)

for all \( \mathbf{x} \in \mathbb{R}_+^n \), where \( \mathcal{T}_n^\Delta (\mathbf{x}) \) denotes the set of all triangular arrays \( \mathbf{z} \) of depth \( n \) with positive entries and \( n \)-th row equal to \( \mathbf{x} \), and

\[
\text{type}(\mathbf{z})^\alpha := \prod_{i=1}^{n} \text{type}(\mathbf{z})_i^{\alpha_i}.
\]

For example, \( \Psi^{\mathfrak{gl}_1}_\alpha (x) = x^\alpha \), and

\[
\Psi^{\mathfrak{gl}_2}_{(\alpha_1,\alpha_2)} (x_1, x_2) = \int_{\mathbb{R}_+} z^{\alpha_1} \left( \frac{x_1 x_2}{z} \right)^{\alpha_2} \exp \left( - \frac{x_2}{z} - \frac{z}{x_1} \right) \frac{dz}{z}.
\]

(2.5)
The representation of $\mathfrak{gl}_n$-Whittaker functions in Definition \ref{def:whittaker} has a recursive structure: setting $\Psi_{\tilde{\alpha}}^\beta(\varnothing) := 1$, it turns out that for all $n \geq 1$, $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{C}^n$ and $x = (x_1, \ldots, x_n) \in \mathbb{R}^n_+$

$$\Psi_{\alpha}^\beta(x) = \int_{\mathbb{R}^n_+} Q_{\alpha_n}^\beta(x, u) \Psi_{\tilde{\alpha}}^{\beta-1}(u) \prod_{j=1}^{n-1} \frac{du_j}{u_j},$$

(2.6)

where $\tilde{\alpha} := (\alpha_1, \ldots, \alpha_{n-1})$ and the kernel is defined by

$$Q_{\alpha_n}^\beta(x, u) = \left( \prod_{j=1}^n x_j \right)^{\alpha_n} \prod_{j=1}^{n-1} \exp \left( -\frac{x_{j+1} - u_j}{x_j} \right).$$

An easy-to-deduce property of $\mathfrak{gl}_n$-Whittaker functions, which will be useful for us, is that for $c \in \mathbb{C}$

$$\Psi_{\alpha+c}^\beta(x) = \left( \prod_{i=1}^n x_i \right)^c \Psi_{\alpha}^\beta(x),$$

(2.7)

where $\alpha + c$ stands for $(\alpha_1 + c, \ldots, \alpha_n + c)$. Another property of Whittaker functions, which is not obvious from the integral formula, but comes from their construction, is that they are invariant under the action of the corresponding Weyl group on the (spectral) parameters $\alpha$.

For the case of $\mathfrak{gl}_n$-Whittaker this means that $\Psi_{\alpha}^\beta(\cdot)$ is invariant under permutation of the entries of $\alpha = (\alpha_1, \ldots, \alpha_n)$.

There is a distinguished differential operator diagonalized by $\mathfrak{gl}_n$-Whittaker function, which is the quantum Toda hamiltonian. In particular, if we set $\psi_{\lambda}^\beta_n(x_1, \ldots, x_n) := \Psi_{\lambda_n}^\beta(e^{x_1}, \ldots, e^{x_n})$, then $\psi_{\lambda}^\beta_n$ is the unique eigenfunction with moderate growth of the operator

$$-\Delta + 2 \sum_{i=1}^{n-1} e^{-(a_i - a_{i+1})},$$

with eigenvalue $-|\lambda|^2 := -\sum_{i=1}^n \lambda_i^2$. Here $a_i \in \mathbb{R}^n$ ($i = 1, \ldots, n-1$) are the positive roots of the Lie group $GL_n(\mathbb{R})$, i.e., $\langle a_i, x \rangle = x_{i+1} - x_i$. As eigenfunctions of a self-adjoint operator, Whittaker functions come with a harmonic analysis, which is very useful for our purposes and is summarized in

**Theorem 2.2** \cite{STS94, KL01}. \textit{The integral transform}

$$\hat{f}(\lambda) := \int_{\mathbb{R}^n_+} f(x) \psi_{\lambda}^\beta_n(x) \prod_{i=1}^n \frac{dx_i}{x_i}$$

defines an isometry from $L^2(\mathbb{R}^n_+, \prod_{i=1}^n dx_i/x_i)$ to $L^2_{\text{sym}}(i\mathbb{R}^n, s_n(\lambda)d\lambda)$, where $\iota = \sqrt{-1}$, $L^2_{\text{sym}}$ denotes the space of square integrable functions that are symmetric in their variables, and

$$s_n(\lambda) := \frac{1}{(2\pi\iota)^n n!} \prod_{i \neq j} (\lambda_i - \lambda_j)^{-1}$$

(2.8)

is the density of the Sklyanin measure. Namely, for all $f, g \in L^2(\mathbb{R}^n_+, \prod_{i=1}^n dx_i/x_i)$ it holds that

$$\int_{\mathbb{R}^n_+} f(x) g(x) \prod_{i=1}^n \frac{dx_i}{x_i} = \int_{i\mathbb{R}^n} \hat{f}(\lambda) \overline{\hat{g}(\lambda)} s_n(\lambda)d\lambda.$$
The case \( n = 1 \).

\[
\begin{array}{c}
z_{1,1} \\
\downarrow \\
z_{2,1}
\end{array}
\]

(a) The case \( n = 1 \).

\[
\begin{array}{c}
z_{1,1} \\
\downarrow \\
z_{2,1} \\
\downarrow \\
z_{2,2} \\
\downarrow \\
z_{3,1} \\
\downarrow \\
z_{3,2}
\end{array}
\]

(b) The case \( n = 2 \).

Figure 3. Half-triangular arrays as in (2.10). The arrows refer to formula (2.11): \( E^a(z) \) is the sum of all \( a/b \) such that there is an arrow pointing from \( a \) to \( b \) in the diagram. The convention is that all the numbers on the vertical wall are 1, so that the only inhomogeneous addends in \( E^b(z) \) are \( 1/z_{2k-1,k} \) for \( 1 \leq k \leq n \).

The computation of certain integrals of Whittaker functions plays an important role in the theory of \( L \)-functions, as it is related to certain functional equations [Bum84]. One such integral formula was conjectured by Bump [Bum84] and proved for \( \mathfrak{gl}_3 \) and in the general case by Stade [Sta02]. This is the following

Theorem 2.3. Suppose \( r > 0 \) and \( \alpha, \beta \in \mathbb{C}^n \) such that \( \Re(\alpha_i + \beta_j) > 0 \) for all \( i, j \). Then

\[
\int_{\mathbb{R}^n_+} e^{-rx} \Psi_{\alpha}^{\mathfrak{gl}_n}(x) \Psi_{\beta}^{\mathfrak{gl}_n}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i} = \left( - \sum_{k=1}^{n} (\alpha_k + \beta_k) \right) \prod_{i,j=1}^{n} \Gamma(\alpha_i + \beta_j). \tag{2.9}
\]

A bijective proof of identity (2.9) was given in [OSZ14] via the use of the geometric RSK correspondence. Subsequently, together with Theorem 2.2, this identity played an important role in the computation of the Laplace transform of the point-to-point partition function of the log-gamma polymer.

2.2. \( \mathfrak{so}_{2n+1} \)-Whittaker Functions. Similarly to the \( \mathfrak{gl}_n \) case, we will define \( \mathfrak{so}_{2n+1} \)-Whittaker functions as integrals of half-triangular arrays. Such definition was first given in [GLO07, GLO08] but also emerged naturally in [Nte17] in the study of a system of interacting particles via intertwining and Markovian dynamics. Let \( n \geq 1 \), and let us consider a half-triangular array of depth \( 2n \)

\[
z = (z_{i,j}: 1 \leq i \leq 2n, \ 1 \leq j \leq [i/2]) \tag{2.10}
\]

with positive entries; examples are given in Figure 3. These arrays correspond to symplectic Gelfand-Tsetlin patterns [Sun90], when the entries are interlaced, that is

\[
z_{i+1,j+1} \leq z_{i,j} \leq z_{i+1,j} \quad \text{for} \ 1 \leq i \leq 2n - 1, \ 1 \leq j \leq [i/2],
\]

with the understanding that \( z_{i,j} \) is set to be zero when \( (i, j) \notin \{1 \leq i \leq 2n, \ 1 \leq j \leq [i/2]\} \). As in the \( \mathfrak{gl}_n \) case, we will be working with half-triangular arrays that do not satisfy the interlacing condition (2.10) but are, nevertheless, encouraged to do so through the potential

...

(see Figure 3 for a graphical representation)

\[
E^\beta(z) := \sum_{i=1}^{2n-1} \sum_{j=1}^{[i/2]} \left( \frac{z_{i+1,j+1}}{z_{i,j}} + \frac{z_{i,j}}{z_{i+1,j}} \right),
\]

(2.11)

with the convention that \( z_{i,j} := 1 \) if \( j > \lceil i/2 \rceil \).

We call \( i \)-th row of \( z \) the vector \((z_{i,1}, \ldots, z_{i,\lceil i/2 \rceil})\) of all entries with first index equal to \( i \) and we denote by \( T^z_{2n}(x) \) the set of all half-triangular arrays \( z \) of depth \( 2n \) with positive entries and bottom row equal to \( x \). We also define the type, \( \text{type}(z) \in \mathbb{R}_{2n}^+ \), as the vector whose \( i \)-th component is the ratio between the product of the \( i \)-th row elements of \( z \) and the product of its \((i - 1)\)-th row elements; in other words,

\[
\text{type}(z)_i := \frac{\prod_{j=1}^{\lceil i/2 \rceil} z_{i,j}}{\prod_{j=1}^{\lceil (i-1)/2 \rceil} z_{i-1,j}} \quad \text{for } i = 1, \ldots, 2n.
\]

Finally, for \( \beta = (\beta_1, \ldots, \beta_n) \in \mathbb{C}^n \), we define \( \beta^\pm \in \mathbb{C}^{2n} \) by

\[
\beta^\pm := (\beta_1, -\beta_1, \beta_2, -\beta_2, \ldots, \beta_n, -\beta_n).
\]

We are now able to define the orthogonal Whittaker functions via an integral representation [GLO07, GLO08].

**Definition 2.4.** The so\(_{2n+1}\)-Whittaker function with parameter \( \beta \in \mathbb{C}^n \) is given by

\[
\Psi^{\text{so}_{2n+1}}_\beta(x) := \int_{T^z_{2n}(x)} \text{type}(z)^{\beta^\pm} \exp \left( -E^\beta(z) \right) \prod_{1 \leq i \leq 2n, 1 \leq j \leq \lceil i/2 \rceil} \frac{dz_{i,j}}{z_{i,j}},
\]

(2.12)

for all \( x \in \mathbb{R}_+^n \), where \( T^z_{2n}(x) \) denotes the set of all half-triangular arrays \( z \) of depth \( 2n \) with positive entries and \((2n)\)-th row equal to \( x \), and

\[
\text{type}(z)^{\beta^\pm}_i := \prod_{k=1}^{2n} \text{type}(z)^{\beta^\pm}_k = \prod_{k=1}^{n} \text{type}(z)^{\beta_{2k-1}}_{2k-1} \text{type}(z)^{-\beta_{2k}}_{2k}.
\]

Again, even though not obvious from this definition, \( \Psi^{\text{so}_{2n+1}}_\beta(\cdot) \) is invariant under permutations and reflections of the (spectral) parameters \( \beta = (\beta_1, \ldots, \beta_n) \), where by reflection we mean multiplication of the entries of \( \beta \) by \( \pm 1 \).

As an example, the so\(_3\)-Whittaker function is given by

\[
\Psi^{\text{so}_3}_\beta(x) = \int_{\mathbb{R}_+^3} \left( \frac{z}{x} \right)^\beta \exp \left( -\frac{1}{z} - \frac{z}{x} \right) \frac{dz}{z}.
\]

(2.13)

The recursive structure of so\(_{2n+1}\)-Whittaker functions is

\[
\Psi^{\text{so}_{2n+1}}_\beta(x) = \int_{\mathbb{R}_+^{n-1}} Q^{\text{so}_{2n+1}}_{\beta_n}(x, u) \Psi^{\text{so}_{2n-1}}_\beta(u) \prod_{j=1}^{n-1} \frac{du_j}{u_j},
\]

(2.14)
for all \( n \geq 1 \), \( \beta = (\beta_1, \ldots, \beta_n) \in \mathbb{C}^n \), \( \hat{\beta} := (\beta_1, \ldots, \beta_{n-1}) \) and \( x = (x_1, \ldots, x_n) \in \mathbb{R}^n_+ \), where we set \( \Psi_{g_\beta}^q(\varnothing) := 1 \) and the kernel \( Q_{\beta_n}^{g_{2n+1}} \) is defined by

\[
Q_{\beta_n}^{g_{2n+1}}(x, u) := \int_{\mathbb{R}_+^n} \left( \prod_{j=1}^n \frac{v_j^2}{u_j} \right)^{\beta_n-1} \prod_{j=1}^n \exp \left( -\frac{v_{j+1}}{u_j} - \frac{v_j}{u_j} \right) \prod_{j=1}^n \exp \left( -\frac{x_{j+1}}{v_j} - \frac{x_j}{v_j} \right) \prod_{j=1}^n \frac{dv_j}{v_j},
\]

with the convention that \( x_{n+1} := 1 \). Similarly to the \( \mathfrak{gl}_n \) case, \( g_{2n+1} \)-Whittaker functions are eigenfunctions of the quantum Toda hamiltonian of type \( B \)

\[
-\Delta + 2 \sum_{i=1}^{n-1} e^{-\langle b_i, x \rangle} + e^{-\langle b_n, x \rangle}.
\]

Here \( b_i \in \mathbb{R}^n \) \( (i = 1, \ldots, n) \) are the positive roots of the Lie group \( SO_{2n+1}(\mathbb{R}) \), i.e. \( \langle b_i, x \rangle = x_{i+1} - x_i \) for \( i = 1, \ldots, n-1 \) and \( \langle b_n, x \rangle = x_n \).

The following integral identity, which will play an important role in our polymer analysis and is of similar nature as the Bump-Stade identity (2.9), has been proven by Ishii and Stade \([IS13]\):

**Theorem 2.5.** Let \( \alpha, \beta, \in \mathbb{C}^n \), where \( \Re(\alpha_i) > |\Re(\beta_j)| \) for all \( i, j \). Then

\[
\int_{\mathbb{R}_+^n} \Psi_{g_\alpha}(x) \Psi_{g_\beta}^{g_{2n+1}}(x) \prod_{i=1}^n dx_i = \frac{\prod_{1 \leq i \leq j \leq n} \Gamma(\alpha_i + \beta_j) \Gamma(\alpha_i - \beta_j)}{\prod_{1 \leq i < j \leq n} \Gamma(\alpha_i + \alpha_j)}. \tag{2.15}
\]

Note that, thanks to the restriction on the parameters in the above formula, the arguments of all Gamma functions on the right-hand side have positive real parts. Let us point out that the parametrization used for Whittaker functions in number theory (in particular in \([IS13]\)) is different from ours. In Appendix \([A]\) we will show the correspondence between the different parametrizations and the equivalence between (2.15) and the corresponding integral formulae in \([IS13]\).

### 3. Laplace Transforms of Point-to-Line Partition Functions

In this section, we compute the Laplace transform of the point-to-line, the point-to-half-line and the restricted point-to-half-line log-gamma polymer partition functions at any even time \( 2n \). We first express these as integrals involving Whittaker functions and next as contour integrals of Gamma functions.

In order to study the distribution of point-to-line partition functions, we first need the joint law of the point-to-point partition functions along a “fixed time” line. This can be done by using the geometric Robinson-Schensted-Knuth correspondence (gRSK) for polygonal arrays and its properties, as these were established in \([NZ15]\). We start by recalling the gRSK construction via local moves and its relevant properties. We should note that the inductive procedure for gRSK that we present here is a little different from the inductions presented in \([NZ15], [OSZ14]\).

#### 3.1. Geometric RSK

The gRSK is a bijective map between polygonal arrays with positive entries, which can be defined as a sequence of local moves. A **polygonal array** is defined to be an array \( t = \{ t_{i,j} : (i, j) \in \mathcal{I} \} \) with positive entries and indexed by a finite set \( \mathcal{I} \subseteq \mathbb{N} \times \mathbb{N} \) satisfying: if \( (i, j) \in \mathcal{I} \), then \( (i-1, j) \in \mathcal{I} \) if \( i > 1 \), and \( (i, j-1) \in \mathcal{I} \) if \( j > 1 \). We denote by \( \mathcal{A}_\mathcal{I} \) the set of all polygonal arrays indexed by \( \mathcal{I} \). We say that \( (i, j) \in \mathcal{I} \) is a **border**
index for \( I \), or for \( t \in A_I \), if not all three sites \((i,j+1), (i+1,j), (i+1,j+1)\) belong to \( I \); we call it outer index if, furthermore, \( \{(i,j+1), (i+1,j), (i+1,j+1)\} \cap I = \emptyset \). We denote the set of outer indices of \( I \) by \( I_{\text{outer}} \). See Figure 4 for a graphical interpretation of \( t \) and its (outer) border indices.

We now construct the gRSK map explicitly. Define first the following maps acting on \( w \in A_I \), with the convention that \( w_{0,j} = w_{i,0} = 0 \) but \( w_{1,0} + w_{0,1} = 1 \):

- for all \((i,j) \in I\), \( a_{i,j} \) replaces \( w_{i,j} \) with
  \[
  w_{i,j} (w_{i-1,j} + w_{i,j-1})
  \]
  and leaves all other entries of \( w \) unchanged;

- for all non-border indices \((i,j) \in I\), \( b_{i,j} \) replaces \( w_{i,j} \) with
  \[
  \frac{1}{w_{i,j}} (w_{i-1,j} + w_{i,j-1}) \left( \frac{1}{w_{i+1,j}} + \frac{1}{w_{i,j+1}} \right)^{-1}
  \]
  and leaves all other entries of \( w \) unchanged.

Operations \( b_{i,j} \) and \( a_{i,j} \) are related to Bender-Knuth transformations and in the setting of geometric RSK correspondence were first introduced by Kirillov [K01]. We now define the operation

\[
\varrho_{i,j} := \bigcirc_{k \geq 1} \circ b_{i-k,j-k} \circ a_{i,j},
\]

where \( \bigcirc_{k \geq 1} \) indicates a sequence of compositions in which \( b_{i-k,j-k} \) appears in the composition only if \((i-k, j-k) \in I\). The maps \( a_{i,j} \)'s and \( b_{i,j} \)'s are called local moves because they act on arrays only locally (see Figure 5A). It is also clear from this figure that two local moves indexed by \((i,j)\) and \((i',j')\) commute if \(|i-i'| + |j-j'| > 1\). Consequently, the order of the sequence of local moves making up a single \( \varrho_{i,j} \) does not matter. Moreover, \( \varrho_{i,j} \) and \( \varrho_{i',j'} \) commute whenever the diagonals that \((i,j)\) and \((i',j')\) belong to are neither the same nor consecutive, i.e. \(|(j-i) - (j'-i')| > 1\).
Figure 5. Graphical representation of how local moves $a_{i,j}$’s and $b_{i,j}$’s and maps $\varrho_{i,j}$’s that compose the $gRSK$ correspondence act on a polygonal array. The arrows point from a node involved in the definition of a local move to a colored node, which corresponds to the entry that is modified by the local move. One can see that any two local moves commute if they are indexed by lattice vertices that are not nearest neighbors, and any two maps $\varrho_{i,j}$’s commute if they are indexed by vertices that do not belong to neighboring diagonals.

Given a set of indices $\mathcal{I}$, we construct the $gRSK$: $A_{\mathcal{I}} \rightarrow A_{\mathcal{I}}$ inductively as follows: We start by $gRSK(\emptyset) := \emptyset$. Let $\mathcal{I}_{\text{out}}$ be the set of outer indices of $\mathcal{I}$ and $\mathcal{I}^\circ := \mathcal{I} \setminus \mathcal{I}_{\text{out}}$. For $w \in A_{\mathcal{I}}$ we define

$$gRSK(w) := \bigcirc_{(i,j) \in \mathcal{I}_{\text{out}}} \varrho_{i,j} \left( gRSK(w^\circ) \sqcup w^{\text{out}} \right),$$

where $w^\circ = \{ w_{i,j} : (i,j) \in \mathcal{I}^\circ \}$, $w^{\text{out}} = \{ w_{i,j} : (i,j) \in \mathcal{I}_{\text{out}} \}$ and $\sqcup$ denotes concatenation. In words, $gRSK$ is first applied to the array $w^\circ$, ignoring entries $w^{\text{out}}$, and then the output is concatenated with the entries $w^{\text{out}}$ and subsequently the maps $\varrho_{i,j}, (i,j) \in \mathcal{I}_{\text{out}}$ are applied to the new array.

We note that since distinct outer indices are never on the same diagonal nor on consecutive diagonals, all $\varrho_{i,j}$’s indexed by the outer indices of a given array commute and so the order in which these maps are composed in (3.1) is irrelevant.

In order to state the main properties of $gRSK$, it is convenient to introduce the following definitions. We denote by $\tau_k$ the product of all elements on the $k$-th diagonal of $t$:

$$\tau_k := \prod_{(i,j) \in \mathcal{I}, \ j-i=k} t_{i,j}.$$  \hspace{1cm} (3.2)

We set the energy of $t$ to be

$$\mathcal{E}(t) := \frac{1}{t_{1,1}} + \sum_{(i,j) \in \mathcal{I}} \frac{t_{i-1,j} + t_{i,j-1}}{t_{i,j}},$$

with the convention that $t_{i,j} := 0$ when $(i,j) \notin \mathcal{I}$. See Figure 4 for a graphical interpretation of the energy of $t$.

Proposition 3.1 ([NZ15 Prop. 2.6, 2.7]). Let $w \in A_{\mathcal{I}}$, $t := gRSK(w)$ and let $(p,q) \in \mathcal{I}$ be a border index. Then
(i) If $\Pi_{p,q}$ is the set of all directed paths from $(1,1)$ to $(p,q)$, then

$$t_{p,q} = \sum_{\pi \in \Pi_{p,q}} \prod_{(i,j) \in \pi} w_{i,j}.$$ 

(ii) If $(p-1,q)$ is a border index or $p = 1$, then

$$\prod_{j=1}^{q} w_{p,j} = \frac{\tau_{q-p}}{\tau_{q-p+1}}.$$ 

Analogously, if $(p,q-1)$ is a border index or $q = 1$, then

$$\prod_{i=1}^{p} w_{i,q} = \frac{\tau_{q-p}}{\tau_{q-p-1}}.$$ 

(iii) It holds that

$$\sum_{(i,j) \in I} \frac{1}{w_{i,j}} = \mathcal{E}(t).$$

(iv) The transformation

$$(\log w_{i,j}, (i,j) \in I) \mapsto (\log t_{i,j}, (i,j) \in I)$$

has Jacobian equal to $\pm 1$.

Property (i) explains how the point-to-point polymer partition functions can be expressed in terms of the $gRSK$ correspondence. In light of this connection, the other properties turn out to be useful in computations related to the log-gamma polymer, as it will become clear soon. We also remark that property (ii) is easily seen to be equivalent to the following: if $(p,q)$ is a border index, then

$$\prod_{i=1}^{p} \prod_{j=1}^{q} w_{i,j} = \tau_{q-p}. \quad (3.4)$$

3.2. POINT-TO-LINE POLYMER. The exactly solvable parametrization of the inverse-gamma variables in the point-to-line geometry is given by

**Definition 3.2.** An $(\alpha, \beta, \gamma)$-log-gamma measure on the lattice $\{(i,j): i + j \leq 2n + 1\}$ is the law of a family of independent random variables $\{W_{i,j}: i + j \leq 2n + 1\}$ distributed as follows:

$$W_{i,j}^{-1} \sim \begin{cases} 
\Gamma(\alpha_i + \beta_j + \gamma + 1) & 1 \leq i, j \leq n, \\
\Gamma(\alpha_i + \alpha_{2n-j+1}) & 1 \leq i \leq n, \ n < j \leq 2n - i + 1, \\
\Gamma(\beta_{2n-i+1} + \beta_j) & 1 \leq j \leq n, \ n < i \leq 2n - j + 1,
\end{cases} \quad (3.5)$$

for some $\alpha, \beta \in \mathbb{R}^n_+$ and $\gamma \geq 0$.

**Remark 3.3.** The choice of the parameters in Definition 3.2 is tailored so that it fits the link between Whittaker functions and $gRSK$. In particular, this is due to property (ii) in Proposition 3.1 and the presence of the type of geometric Gelfand-Tsetlin patterns in the integral formula for Whittaker functions, cf. Definitions 2.1 and 2.4. This will become clear in the proofs of Lemmas 3.4 and 3.6 below. We have also included an extra parameter $\gamma$ in the distribution of the weights $W_{i,j}$ for $1 \leq i, j \leq n$. This might seem rather unnatural,
but it will turn out to be useful in the proof of Theorem \ref{thm:polymer} to obtain contour integral formulae. More specifically, the Plancherel theorem for g$_{\alpha \tau}$Whittaker functions can be applied in \cite{BZ2018} thanks to estimation \ref{est:plancherel}, which in turn relies on the presence of the parameter $\gamma$ in \ref{def:gamma}.

We first compute the joint law of all the point-to-point partition functions at a fixed time horizon. The next proposition is a modification of \cite[Thm 3.5]{NZ2015}, which accommodates the extra parameter $\gamma$ in Definition \ref{def:gamma}.

**Lemma 3.4.** For the $(\alpha, \beta, \gamma)$-log-gamma polymer, the joint distribution of the point-to-point partition functions at time $2n$ is

$$
P(Z_{t,2n+1-i} \in dx \; \forall i = 1, \ldots, 2n) = \frac{1}{\Gamma_{\alpha,\beta,\gamma}} \Phi_{\alpha,\beta,\gamma}(x) \prod_{i=1}^{2n} dx_i$$  \hfill (3.6)

for $x \in \mathbb{R}^{2n}_+$. The normalization constant $\Gamma_{\alpha,\beta,\gamma}$ and the function $\Phi_{\alpha,\beta,\gamma}$ are given by

$$
\Gamma_{\alpha,\beta,\gamma} := \prod_{1 \leq i < j \leq n} \Gamma(\alpha_i + \beta_j + \gamma) \prod_{1 \leq i \leq n} \Gamma(\alpha_i + \alpha_j) \Gamma(\beta_i + \beta_j), \hfill (3.7)
$$

and

$$
\Phi_{\alpha,\beta,\gamma}(x) := \int_{T_{2n}^n(x)} \tau_0 \prod_{k=1}^{n} \left( \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2} \tau_{2n-2k}} \right)^{-\alpha_k} \left( \frac{\tau_{2n-2k-1}}{\tau_{2n-2k+2} \tau_{2n-2k}} \right)^{-\beta_k} e^{-E(t)} \prod_{i+j \leq 2n} dt_{i,j}, \hfill (3.8)
$$

where $T_{2n}^n(x)$ denotes the set of all triangular arrays $t = \{t_{i,j} : i + j \leq 2n + 1\} \in \mathbb{R}^{(2n+1)}_+$.

**Proof.** Set $I := \{(i, j) \in \mathbb{N} \times \mathbb{N} : i + j \leq 2n + 1\}$. According to \ref{eq:jointlaw}, the joint law of the weight triangular array $W = \{W_{i,j} : (i, j) \in I\}$ for the $(\alpha, \beta, \gamma)$-log-gamma measure is given by

$$
P(W \in dw) = \prod_{i,j=1}^{n} \frac{w_{i,j}^{-\alpha_i - \beta_j - \gamma}}{\Gamma(\alpha_i + \beta_j + \gamma)} \prod_{1 \leq i \leq n} \frac{w_{i,j}^{-\alpha_i - \alpha_{2n-j+1}}}{\Gamma(\alpha_i + \alpha_{2n-j+1})} \prod_{1 \leq j \leq n} \frac{w_{i,j}^{-\beta_{2n-i+1} - \beta_j}}{\Gamma(\beta_{2n-i+1} + \beta_j)} \times \exp \left( - \sum_{(i,j) \in I} \frac{1}{w_{i,j}} \right) \prod_{(i,j) \in I} dw_{i,j} \hfill (3.9)
$$

We now rewrite the above in terms of the image array $T = \{T_{i,j} : (i, j) \in I\}$ of $W$ under the gRSK bijection. By formula \ref{eq:product}, the product of $w_{i,j}$'s that are raised to power $-\gamma$ is $\prod_{i,j=1}^{n} w_{i,j} = \tau_0$. Property (i) of Proposition \ref{prop:gamma} yields

$$
\prod_{j=1}^{2n-k+1} w_{k,j} = \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2}}, \quad \prod_{i=1}^{2n-k+1} w_{i,k} = \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2}} 
$$

for $1 \leq k \leq 2n$ with the convention that $\tau_{2n} = \tau_{-2n} = 1$. The product of all $w_{i,j}$'s that are raised to power $-\alpha_k$ in \ref{eq:product} is written as

$$
\prod_{j=1}^{2n-k+1} w_{k,j} \prod_{i=1}^{k} w_{i,2n-k+1} = \frac{\tau_{2n-2k+1} \tau_{2n-2k+1}}{\tau_{2n-2k+2} \tau_{2n-2k}},
$$
Theorem 3.5. Given that \( Z_{2n} = \sum_{i=1}^{2n} Z_{i, 2n-i+1} \) and \( Z_{i, 2n-i+1} \) are raised to power \( -\beta \), the product of all \( w_{i,j} \)'s that are raised to power \( -\beta \) is written as

\[
\prod_{i=1}^{2n-k+1} w_{i,k} \prod_{j=1}^{k} w_{2n-k+1, j} = \frac{\tau_{-2n+2k-1} \tau_{-2n+2k-1}}{\tau_{-2n+2k-2} \tau_{-2n+2k}}.
\]

Using property (iii) of Proposition 3.1 for dealing with the exponential term in (3.9), and property (iv) regarding the volume preserving property of the differential form, we obtain:

\[
P(\mathcal{T} \in dt) = \prod_{1 \leq i,j \leq n} \Gamma(\alpha_i + \beta_j + \gamma) \prod_{1 \leq i,j \leq n} \Gamma(\alpha_i + \alpha_j) \Gamma(\beta_i + \beta_j) \times \tau_0^{-\gamma} \prod_{k=1}^{n} \left( \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2} \tau_{2n-2k-2}} \right)^{-\alpha_k} \left( \frac{\tau_{2n+2k-1}}{\tau_{-2n+2k-2} \tau_{-2n+2k+2}} \right)^{-\beta_k} e^{-\mathcal{E}(t)} \prod_{(i,j) \in \mathcal{T}} dt_{i,j}.
\]

Finally, property (i) of Proposition 3.1 allows one to write the joint law of \((Z_{1,2n}, Z_{2,2n-1}, \ldots, Z_{2n,1})\) as in (3.6) by integrating the above over \( T_{2n}^{\text{flat}}(x) \).

We can now derive the Whittaker integral formula for the Laplace transform of \( Z_{2n}^{\text{flat}} \).

**Theorem 3.5.** The Laplace transform of the point-to-line partition function \( Z_{2n}^{\text{flat}} \) for the \((\alpha, \beta, \gamma)\)-log-gamma polymer can be written in terms of orthogonal Whittaker functions as:

\[
\mathbb{E}[e^{-rZ_{2n}^{\text{flat}}}] = \frac{\sum_{i=1}^{n} (\alpha_i + \beta_i + \gamma)}{\Gamma_{\alpha, \beta, \gamma}} \int_{\mathbb{R}^n} e^{-r \sum_{i=1}^{n} x_i} \prod_{i=1}^{n} \Psi_{2n+1}^{\alpha_i}(x) \Psi_{\beta_i}^{2n+1}(x) dx_i
\]

for all \( r > 0 \), where \( \Gamma_{\alpha, \beta, \gamma} \) is defined by (3.7).

**Proof.** Given that \( Z_{2n}^{\text{flat}} = \sum_{i=1}^{2n} Z_{i, 2n-i+1} \) and \( Z_{i, 2n-i+1} \) are raised to power \( -\beta \), the product of all \( w_{i,j} \)'s that are raised to power \( -\beta \) is written as

\[
\prod_{i=1}^{2n-k+1} w_{i,k} \prod_{j=1}^{k} w_{2n-k+1, j} = \frac{\tau_{-2n+2k-1} \tau_{-2n+2k-1}}{\tau_{-2n+2k-2} \tau_{-2n+2k}}.
\]

Using definition (3.8) of \( \Phi_{\alpha, \beta, \gamma}^{\text{flat}} \) and expressing part of the integrand in the right hand side in terms of variables \( t_{i,j} \)'s of the corresponding triangular array (recall notations (3.2), (3.3)), we obtain

\[
\mathbb{E}[e^{-rZ_{2n}^{\text{flat}}}] = \frac{1}{\Gamma_{\alpha, \beta, \gamma}} \int_{\mathbb{R}^n} \prod_{i=1}^{2n} dt_{i,2n-i+1} \exp \left( -r \sum_{i=1}^{2n} t_{i,2n-i+1} \right) \prod_{i=1}^{2n} \prod_{j=1}^{i} \prod_{j>1}^{i} \prod_{j=1}^{i} \prod_{i+j \leq 2n} dt_{i,j},
\]

where the implicit range of indices for \( (i, j) \) is \( i + j \leq 2n + 1 \). We now change variables by setting

\[
t_{i,j} = (rs_{i,j})^{-1}, \quad \text{for all } (i, j).
\]

Pictorially, this change of variables reverses the arrows in Figure 4A. This can be seen if one recalls (see caption of Figure 4) that an “arrow” \( t_{i,j} \rightarrow t_{i+1,j} \) or \( t_{i,j} \rightarrow t_{i,j+1} \) in the figure represents a summand \( t_{i,j}/t_{i+1,j} \) or \( t_{i,j}/t_{i,j+1} \), respectively, in the functional \( \mathcal{E}(t) \). The
change of variables (3.11) will transform these ratios to $t_{i+1,j}/t_{i,j}$ and $t_{i,j+1}/t_{i,j}$, which by
the same convention can be represented in the diagrams as $t_{i+1,j} \to t_{i,j}$ and $t_{i,j+1} \to t_{i,j}$.

Recalling, now, (3.2) we obtain
\[
\left( \frac{\tau^2_{2n-2k+1}}{\tau^2_{2n-2k+2}\tau^2_{2n-2k}} \right)^{-\alpha_k} = \left( \prod_{j-i=2n-2k+2} \frac{t_{i,j}^2}{t_{i,j}^2} \prod_{j-i=2n-2k} \right)^{-\alpha_k} = r^{\alpha_k} \left( \prod_{j-i=2n-2k+2} s_{i,j}^2 \prod_{j-i=2n-2k} s_{i,j}^2 \right) = r^{\alpha_k} \left( \frac{\sigma^2_{2n-2k+1}}{\sigma_{2n-2k+2}\sigma_{2n-2k}} \right)^{\alpha_k},
\]
where analogously to (3.2) we set $\sigma_k := \prod_{j-i=k} s_{i,j}$. Similarly, we have
\[
\left( \frac{\tau^2_{2n+2k-1}}{\tau_{2n-2k-2}\tau_{2n+2k}} \right)^{-\beta_k} = r^{\beta_k} \left( \frac{\sigma^2_{2n+2k-1}}{\sigma_{2n-2k-2}\sigma_{2n+2k}} \right)^{\beta_k} \quad \text{and} \quad \tau_{0}^{-\gamma} = r^{\gamma} \sigma_{0}^{\gamma}.
\]
Moreover, the volume is preserved under this change of variables, that is
\[
\prod_{i+j \leq 2n} \frac{dt_{i,j}}{t_{i,j}} = \prod_{i+j \leq 2n} \frac{ds_{i,j}}{s_{i,j}}.
\]

We thus obtain
\[
\mathbb{E}[e^{-rZ_{2n}^{\text{flat}}}] = \frac{\sum_{k=1}^{n}(\alpha_k + \beta_k + \gamma)}{\Gamma_{\alpha,\beta,\gamma}} \int_{\mathbb{R}_{+}^{2n}} \prod_{i=1}^{2n} ds_{i,2n-i+1} \exp \left( -\sum_{i=1}^{n} \frac{1}{s_{i,2n-i+1}} \right) \\
\times \int_{\mathbb{R}_{+}^{(2n-1)\alpha}} \sigma_{0}^{\frac{n}{k=1}} \prod_{k=1}^{n} \left( \frac{\sigma_{2n-2k+1}}{\sigma_{2n-2k+2}\sigma_{2n-2k}} \right)^{\alpha_k} \left( \frac{\sigma_{2n+2k-1}}{\sigma_{2n-2k-2}\sigma_{2n+2k}} \right)^{\beta_k} \\
\times \exp \left( -r s_{1,1} - \sum_{i=1,j<i} s_{i,j} - \sum_{j=1,i<j} s_{i,j} \right) \prod_{i+j \leq 2n} \frac{ds_{i,j}}{s_{i,j}}.
\]

We now change the order in which variables are integrated in the above expression: we first integrate over the two triangular arrays $\{s_{i,j}\}_{i \leq j}$ and $\{s_{i,j}\}_{j \leq i}$ into which the whole triangular shape (see Figure 4A) is divided by the main diagonal $\{(i,i): i \geq 1\}$; next, we integrate over the diagonal variables $s_{1,1}, \ldots, s_{n,n}$. This way, we obtain:
\[
\mathbb{E}[e^{-rZ_{2n}^{\text{flat}}}] = \frac{\sum_{k=1}^{n}(\alpha_k + \beta_k + \gamma)}{\Gamma_{\alpha,\beta,\gamma}} \int_{\mathbb{R}_{+}^{n}} \prod_{i=1}^{n} ds_{i,1} \left( \prod_{i=1}^{n} s_{i,i} \right)^{\gamma} e^{-r s_{1,1}} \\
\times \int_{\mathbb{R}_{+}^{2n}} \prod_{k=1}^{n} \left( \frac{\sigma_{2n-2k+1}}{\sigma_{2n-2k+2}\sigma_{2n-2k}} \right)^{\alpha_k} \exp \left( -\sum_{i=1}^{n} \frac{1}{s_{i,2n-i+1}} - \sum_{1<i,j} s_{i,j} \right) \\
\times \prod_{i<j} s_{i,j}^{\beta_k} \left( \sum_{i=1,j<i} s_{i,j} + \sum_{j=1,i<j} s_{i,j} \right) \prod_{i+j \leq 2n} \frac{ds_{i,j}}{s_{i,j}}.
\]
Comparing with Definition 2.4, we identify the second and the third integral in the above formula as $\mathbf{s}_{2n+1}$ Whittaker functions, both with shape variables $s_{1,1}, \ldots, s_{n,n}$ and parameters $\alpha$ and $\beta$ respectively. This concludes the proof of (3.10). \(\square\)
3.3. **Point-to-half-line polymer.** The only weights involved in the point-to-half-line partition function are \( \{W_{i,j} : i \leq n, i + j \leq 2n + 1\} \), see Figure 13. When restricted to such a trapezoidal array, the \((\alpha, \beta, \gamma)\)-log-gamma measure \((3.3)\) coincides with the law of a \((\alpha, \beta + \gamma, 0)\)-log-gamma measure. For this reason, in the following, we will assume without loss of generality that \( \gamma = 0 \) and we will refer to the corresponding model as the half-flat \((\alpha, \beta)\)-log-gamma polymer. We first give an expression for the joint law of the point-to-point partition functions on a “half-line”. Again, the proof will be based on Theorem \[3.1\].

**Lemma 3.6.** For the half-flat \((\alpha, \beta)\)-log-gamma polymer, the joint distribution of the point-to-point partition functions on the half-line \( \{i + j = 2n + 1, i \leq j\} \) is

\[
\mathbb{P}(Z_{i,2n+1-i}^{h-flat} \in dx_i \ \forall i = 1, \ldots, n) = \frac{1}{\Gamma_{h-flat}^{\alpha,\beta}(x)} \prod_{i=1}^{n} \frac{dx_i}{x_i}
\]

for \( x \in \mathbb{R}_+^n \). The normalization constant \( \Gamma_{h-flat}^{\alpha,\beta} \) and the function \( \Phi_{h-flat}^{\alpha,\beta}(x) \) are given by

\[
\Gamma_{h-flat}^{\alpha,\beta} := \prod_{1 \leq i,j \leq n} \Gamma(\alpha_i + \beta_j) \prod_{1 \leq i,j \leq n} \Gamma(\alpha_i + \alpha_j),
\]

\[
\Phi_{h-flat}^{\alpha,\beta}(x) := \int_{\mathbb{T}_{h-flat}^{\alpha,\beta}(x)} \prod_{k=1}^{n} \left( \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2}\tau_{2n-2k}} \right)^{-\alpha_k} \left( \frac{\tau_{n+k}}{\tau_{n+k-1}} \right)^{-\beta_k} e^{-\mathcal{E}(t)} \prod_{i+j \leq 2n} dt_{i,j},
\]

where \( \mathbb{T}_{h-flat}^{\alpha,\beta}(x) \) denotes the set of all trapezoidal arrays \( t = \{(i,j) : i \leq n, i + j \leq 2n + 1\} \in \mathbb{R}^{(3n^2+n)/2} \) with positive entries such that \((t_{1,2n}, t_{2,2n-1}, \ldots, t_{n,n+1}) = x\).

**Proof.** Setting \( I := \{(i,j) \in \mathbb{N} \times \mathbb{N} : i \leq n, i + j \leq 2n + 1\} \), the joint law of the weight trapezoidal array \( W = \{W_{i,j} : (i,j) \in I\} \) for the half-flat \((\alpha, \beta)\)-log-gamma polymer is given by

\[
\mathbb{P}(W \in dw) = \prod_{1 \leq i,j \leq n} w_{i,j}^{-\alpha_i-\beta_j} \prod_{1 \leq i,j \leq n} \frac{\Gamma(\alpha_i + \alpha_j)}{\Gamma(\alpha_i + \alpha_j + 1)} \prod_{n < j \leq 2n-i+1} \frac{w_{i,j}^{-\alpha_i-\alpha_{2n-j+1}}}{\Gamma(\alpha_i + \alpha_{2n-j+1})} \\
\times \exp\left(- \sum_{(i,j) \in I} \frac{1}{w_{i,j}} \right) \prod_{(i,j) \in I} dw_{i,j}.
\]

We now rewrite the above in terms of the image array \( T = \{T_{i,j} : (i,j) \in I\} \) of \( W \) under the gRSK bijection. The powers of \( w_{i,j} \)’s are sorted out by noting that

\[
\prod_{j=1}^{2n-k+1} w_{i,j} = \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2}} \quad \text{and} \quad \prod_{i=1}^{n} w_{i,k} = \frac{\tau_{n+k}}{\tau_{n+k-1}}, \quad \prod_{i=1}^{k} w_{i,2n-k+1} = \frac{\tau_{2n-k+1}}{\tau_{2n-2k}}
\]

for \( 1 \leq k \leq n \), thanks to property \([i]\) of Proposition \[3.1\]. Using property \([iii]\) for dealing with the exponential in \[3.14\], and property \([iv]\) for the differential form, we obtain:

\[
\mathbb{P}(T \in dt) = \prod_{1 \leq i,j \leq n} \frac{1}{\Gamma(\alpha_i + \beta_j)} \prod_{1 \leq i,j \leq n} \frac{1}{\Gamma(\alpha_i + \alpha_j)} \\
\times \prod_{k=1}^{n} \left( \frac{\tau_{2n-2k+1}}{\tau_{2n-2k+2}\tau_{2n-2k}} \right)^{-\alpha_k} \left( \frac{\tau_{n+k}}{\tau_{n+k-1}} \right)^{-\beta_k} e^{-\mathcal{E}(t)} \prod_{(i,j) \in I} dt_{i,j}.
\]
Finally, property (4) allows writing the joint law of \((Z_{1,2n}, Z_{2,2n-1}, \ldots, Z_{n,n+1})\) by integrating the above over \(\mathcal{F}_{2n}(x)\).

**Theorem 3.7.** The Laplace transform of the point-to-half-line partition function \(Z_{2n}^{\text{h-flat}}\) for the half-flat \((\alpha, \beta)\)-log-gamma polymer can be written in terms of Whittaker functions as:

\[
E[e^{-rZ_{2n}^{\text{h-flat}}}] = \frac{\prod_{k=1}^{n} (\alpha_k + \beta_k)}{\Gamma_{\alpha, \beta}} \int_{\mathbb{R}_+^n} e^{-rx_1} \psi_{\alpha, \beta}^{2n+1}(x) \prod_{i=1}^{n} dx_i
\]

for all \(r > 0\), where \(\Gamma_{\alpha, \beta}\) is given by \((3.12)\).

**Proof.** Given that \(Z_{2n}^{\text{h-flat}} = \sum_{i=1}^{n} Z_{i,2n-i+1}\), we have via Lemma 3.6 that

\[
\int e^{-rZ_{2n}^{\text{h-flat}}} = \int e^{-r\sum_{i=1}^{n} Z_{i,2n+1-i}} = \frac{1}{\Gamma_{\alpha, \beta}} \int_{\mathbb{R}_+^n} \exp \left( -r \sum_{i=1}^{n} x_i \right) \Phi_{\alpha, \beta}^{\text{h-flat}}(x) \prod_{i=1}^{n} dx_i.
\]

Using definition \((3.13)\) of \(\Phi_{\alpha, \beta}^{\text{h-flat}}\) and performing the same change of variables \((3.11)\) as in the proof of Theorem 3.5, we obtain

\[
\int e^{-rZ_{2n}^{\text{h-flat}}} = \int e^{-r\sum_{i=1}^{n} Z_{i,2n+1-i}} = \frac{1}{\Gamma_{\alpha, \beta}} \int_{\mathbb{R}_+^n} \exp \left( -r \sum_{i=1}^{n} x_i \right) \Phi_{\alpha, \beta}^{\text{h-flat}}(x) \prod_{i=1}^{n} dx_i.
\]

where the implicit range of indices for \((i, j)\) is \(i \leq n\), \(i + j \leq 2n + 1\), and we set \(s_k := \prod_{j=i+1}^{n} s_{i,j}\). We now change the order in which variables are integrated in the above expression: we first integrate over the two triangular arrays \(\{s_{i,j}\}_{i<j}\) and \(\{s_{i,j}\}_{j<i}\) into which the whole trapezoidal shape (see Figure 1B) is divided by the main diagonal \(\{(i, i); i \geq 1\}\); next, we integrate over the diagonal variables \(s_{1,1}, \ldots, s_{n,n}\). In this way we obtain:

\[
\int e^{-rZ_{2n}^{\text{h-flat}}} = \int e^{-r\sum_{i=1}^{n} Z_{i,2n+1-i}} \prod_{i=1}^{n} s_{i,i} \exp \left( -r s_{1,1} \right) \prod_{i<j} \frac{ds_{i,j}}{s_{i,j}}.
\]

Comparing with Definition 2.4 and 2.1, we identify the second integral as an \(\mathfrak{so}_{2n+1}\)-Whittaker function with parameters \(\alpha\), and the third integral as a \(\mathfrak{gl}_n\)-Whittaker function with parameters \(\beta\), both with shape variables \(s_{1,1}, \ldots, s_{n,n}\). This concludes the proof of \((3.15)\). \qed
Remark 3.8. Taking the limit \( r \to 0 \) in (3.15) and since \( \mathbb{E}[e^{-rZ_{2n}^{\text{flat}}}] \to 1 \) and \( r \sum_{k=1}^{n}(\alpha_k+\beta_k) \to 0 \), we observe that the integral

\[
\int_{\mathbb{R}_+^{2n}} \psi_{\alpha}^{\otimes 2n+1}(x) \psi_{\beta}^{\otimes n}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}
\]
diverges for all \( \alpha, \beta \in \mathbb{R}_+^n \). This does not contradict Ishii-Stade identity, as in (2.15) the parameters of the \( \mathfrak{gl}_n \)-Whittaker function are required to have negative real part.

3.4. Restricted and Symmetric Point-to-Line Polymers. We now study the point-to-line polymer restricted to stay in a half plane, i.e. not allowed to go below the main diagonal. We approach this by noting that the restricted polymer is closely connected to a symmetric polymer, i.e. a polymer whose weight array \( W = \{W_{i,j}, i+j \leq 2n+1\} \) satisfies \( W_{i,j} = W_{j,i} \) for all \( i,j \). Indeed, for each time a given restricted polymer path touches the main diagonal \( i = j \) (including the starting point \((1,1)\)), the symmetric polymer partition function counts the weight of that path twice. Therefore, the partition function of a symmetric polymer is given by:

\[
Z_{2n}^{\text{sym}} = \sum_{\pi \in \Pi_{2n}^{\text{flat}}} 2^\#\{i,i \in \pi\} \prod_{(i,j) \in \pi} W_{i,j} = \sum_{\pi \in \Pi_{2n}^{\text{flat}}} \prod_{(i,j) \in \pi} (1 + \delta_{i,j})W_{i,j},
\]

where \( \Pi_{2n}^{\text{flat}} \) is the set of all paths \( \pi \) of length \( 2n \) starting from \((1,1)\) such that \( i \leq j \) for all \((i,j) \in \pi\) (“restricted” paths). It follows that the partition functions of the symmetric and restricted polymers are equal in distribution when the weights of the restricted polymer are doubled on the diagonal. To see what this practically means in the log-gamma case, we refer the reader to Definition 3.10 and Remark 3.11. Without loss of generality, we may then restrict ourselves to study the symmetric polymer.

We first give the natural definitions of transposition and symmetry in this setting. We define the transpose of an index set \( \mathcal{I} \) as the index set \( \mathcal{I}^\top := \{(i,j) \in \mathbb{N} \times \mathbb{N}: (j,i) \in \mathcal{I}\} \); similarly, we define the transpose \( t^\top \) of a polygonal array \( t \) by setting \( t_{i,j}^\top := t_{j,i} \) for all \((i,j) \in \mathcal{I}^\top \). An index set \( \mathcal{I} \) will be called symmetric if \( \mathcal{I} = \mathcal{I}^\top \), and a polygonal array \( t \) indexed by a symmetric \( \mathcal{I} \) will be called symmetric if \( t = t^\top \).

Properties (i), (ii), (iii) in Proposition 3.1 for the \( \mathfrak{gRSK} \) with respect to input arrays without any symmetry constraint, transfer directly to the case of symmetric arrays. The volume preserving property is also satisfied:

Proposition 3.9. Let \( w \in \mathcal{A}_\mathcal{I} \) and \( t := \mathfrak{gRSK}(w) \). Then \( \mathfrak{gRSK}(w^\top) = t^\top \). In particular, if \( w \) is symmetric, so is \( t \). Moreover, in the symmetric case, the transformation

\[
(\log w_{i,j} : (i,j) \in \mathcal{I}, i \leq j) \mapsto (\log t_{i,j} : (i,j) \in \mathcal{I}, i \leq j)
\]

has Jacobian equal to \( \pm 1 \).

Proof. The fact that \( \mathfrak{gRSK}(w^\top) = \mathfrak{gRSK}(w)^\top \) is an easy consequence of the inductive construction (3.1) of \( \mathfrak{gRSK} \), since local moves are clearly symmetric, in the sense that \( a_{i,j}(w^\top) = a_{i,j}(w)^\top \), and the same holds for \( b_{i,j} \). Let us now check the volume preserving property in the case of symmetric \( w \). In the case of a square symmetric array \( w \), this has been already checked in [OSZ14] Thm 5.2. On the other hand, every symmetric array \( w \) will contain a subarray \( w|_{\mathcal{I}'} \), where \( \mathcal{I}' \) is the biggest square subset of \( \mathcal{I} \) with upper left index \((1,1)\). By the inductive construction (3.1) of \( \mathfrak{gRSK} \), we can obtain the \( \mathfrak{gRSK} \) image of \( w \).
by first applying the $gRSK$ mapping to $w|_{I'}$ and then insert the rest of the entries via a suitable sequence of mappings $g_{k,l}$ with $(k,l) \in I \setminus I'$. Since $I'$ is square, we know that the claim holds for $I'$, i.e. the transformation
\[(\log w_{i,j} : (i,j) \in I', i \leq j) \mapsto (\log t_{i,j} : (i,j) \in I', i \leq j)\]
is volume preserving. Next, we apply the sequence of moves $g_{k,l}$ for $(k,l) \in I \setminus I'$ with $k \leq l$ in the order specified by the inductive construction of $gRSK$. Now, every $(k,l) \in I \setminus I'$ with $k \leq l$ actually satisfies $k < l$ hence, crucially, the corresponding mapping $g_{k,l}$ does not involve any symmetric variables, i.e. acts on the entries indexed by $i \leq j$ only and does not involve entries indexed by $i > j$. It follows that, since all mappings $g_{k,l}$'s are volume preserving in logarithmic variables (as local moves trivially are), after applying all $g_{k,l}$'s with $(k,l) \in I \setminus I'$, the volume of the upper "triangular" part of the array is still preserved, thus leading to the volume preserving property of the map \((3.16)\).

The exactly solvable distribution on symmetric arrays that links to $so_{2n+1}$-Whittaker functions is given by

**Definition 3.10.** For a triangular index set $\{i+j \leq 2n+1\}$ and a symmetric weight array $W = \{W_{i,j} : i + j \leq 2n + 1\}$, we define the symmetric $(\alpha, \gamma)$-log-gamma measure to be the law on $W$ when the entries on or above the diagonal are independent and distributed as

\[W_{i,j}^{-1} \sim \begin{cases} \Gamma(\alpha_i + \gamma, 1/2) & 1 \leq i = j \leq n, \\
\Gamma(\alpha_i + \alpha_j + 2\gamma, 1) & 1 \leq i < j \leq n, \\
\Gamma(\alpha_i + \alpha_{2n-j+1}, 1) & 1 \leq i \leq n, n < j \leq 2n - i + 1, \end{cases} \tag{3.17}\]

for some $\alpha \in \mathbb{R}_+^n$ and $\gamma \geq 0$. We will refer to the directed polymer on such arrays as the symmetric $(\alpha, \gamma)$-log-gamma polymer.

Let us note that the joint law of the upper entries of $W$ is

\[
\mathbb{P}(W_{i,j} \in dw_{i,j} \ \forall i \leq j) = \prod_{i=1}^{n} \frac{w_{i,i}^{-\alpha_i - \gamma}}{\Gamma(\alpha_i + \gamma)} \prod_{1 \leq i < j \leq n} \frac{w_{i,j}^{-\alpha_i - \alpha_j - 2\gamma}}{\Gamma(\alpha_i + \alpha_j + 2\gamma)} \prod_{1 \leq i \leq n, n < j \leq 2n - i + 1} \frac{w_{i,j}^{-\alpha_i - \alpha_{2n-j+1}}}{\Gamma(\alpha_i + \alpha_{2n-j+1})} \exp \left(-\sum_{i=1}^{n} \frac{1}{2w_{i,i}} - \sum_{i<j} \frac{1}{w_{i,j}} \right) \prod_{i<j} dw_{i,j}. \tag{3.18}\]

**Remark 3.11.** Based on the discussion on the relation between symmetric and restricted polymer, we can easily conclude that the exactly solvable measure for a restricted polymer is deduced from the symmetric law and amounts to only modifying the law of the diagonal entries of the latter to $W_{i,i}^{-1} \sim \Gamma(\alpha_i + \gamma, 1)$. We call this measure the restricted $(\alpha, \gamma)$-log-gamma measure and the corresponding restricted polymer the restricted $(\alpha, \gamma)$-log-gamma polymer.

Due to the symmetry of the output array $T = gRSK(W)$, which follows from Proposition \[3.9\] we have that

\[Z_{2n}^{\text{sym}} = 2 \sum_{i=1}^{n} Z_{i,2n-i+1}^{\text{sym}}. \tag{3.19}\]
The next proposition gives the joint law of the point-to-point partition functions in the right hand side. The proof follows the same steps as that of Lemma 3.4 (up to incorporating appropriately the symmetry condition) and so we omit it.

**Lemma 3.12.** For the symmetric $(\alpha, \gamma)$-log-gamma polymer, the joint law of the point-to-point partition functions at time $2n$ is

$$\mathbb{P}(Z_{2n}^{\text{sym}} + 1 \in 2^{-1} dx_i \forall i = 1, \ldots, n) = \frac{1}{\Gamma_{\alpha, \gamma}} \Phi_{\alpha, \gamma}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}$$

for $x \in \mathbb{R}_+^n$. The normalization constant $\Gamma_{\alpha, \gamma}$ and the function $\Phi_{\alpha, \gamma}$ are given by

$$\Gamma_{\alpha, \gamma} := \prod_{i=1}^{n} \left( \int_{T_{2n}^{\text{flat}}(x)} \frac{d\tau}{\tau_0} \right) \prod_{1 \leq i < j \leq n} \frac{\Gamma(\alpha_i + \alpha_j + 2\gamma)}{\Gamma(\alpha_i + \alpha_j)}$$

for $\alpha, \gamma > 0$. The normalization constant $\Gamma_{\alpha, \gamma}$ and the function $\Phi_{\alpha, \gamma}$ are given by

$$\Phi_{\alpha, \gamma}(x) := \int_{T_{2n}^{\text{flat}}(x)} \frac{d\tau}{\tau_0} \prod_{k=1}^{n} \left( \frac{\tau_{2k-2k+1}}{\tau_{2k-2k+2}\tau_{2k-2}} \right)^{-\alpha_k}$$

where the implicit index range is $i + j \leq 2n + 1$, $i \leq j$, and $T_{2n}^{\text{flat}}(x)$ denotes the set of all triangular arrays $\{t_{ij} : i + j \leq 2n + 1, i \leq j\} \in \mathbb{R}^{n(n+1)}$ with positive entries such that $(t_{1,2n}, t_{2,2n-1}, \ldots, t_{n,n+1}) = x$.

Lemma 3.12 allows us to obtain a Whittaker integral formula for the Laplace transform of $Z_{2n}^{\text{sym}}$ and $Z_{2n}^{\text{flat}}$ as stated in the next theorem. The proof is omitted as it follows the same steps as in Theorems 3.5 and 3.7.

**Theorem 3.13.** The Laplace transform of the point-to-line partition functions for the symmetric $(\alpha, \gamma)$-log-gamma polymer and the restricted $(\alpha, \gamma)$-log-gamma polymer, denoted by $Z_{2n}^{\text{sym}}$ and $Z_{2n}^{\text{flat}}$ respectively, can be written in terms of orthogonal Whittaker functions as:

$$\mathbb{E}\left[ e^{-rZ_{2n}^{\text{flat}}} \right] = \mathbb{E}\left[ e^{-rZ_{2n}^{\text{sym}}} \right] = \frac{\prod_{k=1}^{n} \Gamma(\alpha_k + \gamma)}{\Gamma_{\alpha, \gamma}} \int_{\mathbb{R}_+^n} \left( \prod_{i=1}^{n} x_i \right)^{\gamma} e^{-rx_1} \Psi_{\alpha}^{\alpha_{2n+1}}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}$$

for all $r > 0$, where $\Gamma_{\alpha, \gamma}$ is defined by (3.20).

**3.5. Contour Integrals.** We now write the integrals of Whittaker functions obtained in (3.10) and (3.15) as contour integrals.

In formula (3.10) for the Laplace transform of the point-to-line partition function, the integral

$$\int_{\mathbb{R}_+^n} \left( \prod_{i=1}^{n} x_i \right)^{\gamma} e^{-rx_1} \Psi_{\alpha}^{\alpha_{2n+1}}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}$$

is analogous, at least for $\gamma = 0$, to the Bump-Stade identity (2.9), where $g_k$-Whittaker functions are replaced with the corresponding orthogonal ones. However, a closed formula for our integral does not appear in the literature, and there are actually some reasons why one may not expect it to be computable in terms of products and ratios of gamma.
functions, see [Bum89], section 2.6. However, we can still turn formula (3.10) into a contour integral of Gamma functions through the Plancherel theorem of \( gl_n \)-Whittaker function and a combination of both the Bump-Stade and Ishii-Stade identities. The key tool is the following lemma.

**Lemma 3.14.** The \( gl_n \)-Whittaker isometry between the spaces \( L^2(\mathbb{R}^n_+, \prod_{i=1}^n dx_i/x_i) \) and \( L^2_{\text{sym}}(i\mathbb{R}^n, s_n(\lambda) \, d\lambda) \) defined in Theorem 2.8 maps

\[
\begin{align*}
(a) \quad f(x) := e^{-rx_1} \Psi_{\alpha}^{\beta} & \quad \mapsto \quad \hat{f}(\lambda) := r^{-\sum_{i=1}^n (\alpha_i + \alpha_j)} \prod_{1 \leq i, j \leq n} \Gamma(\lambda_i + \alpha_j) \\
(b) \quad g(x) := \left( \prod_{i=1}^n \psi_{\beta}^{\gamma} \right) \Psi_{\alpha}^{\beta} \quad & \quad \mapsto \quad \hat{g}(\lambda) := \prod_{1 \leq i, j \leq n} \Gamma(s - \lambda_i + \beta_j) \frac{\Gamma(s - \lambda_i - \beta_j)}{\Gamma(2s - \lambda_i - \lambda_j)}
\end{align*}
\]

for all \( r > 0 \) and \( \alpha, \beta \in \mathbb{C}^n \) such that \( \Re(\alpha_j) > 0 \) for all \( j \)

**Proof.** (a) Assuming that \( f \) is square-integrable, the Bump-Stade identity (2.9) implies that \( \hat{f} \) is indeed the \( gl_n \)-Whittaker transform of \( f \). To prove that \( f \) belongs to \( L^2(\mathbb{R}^n_+, \prod_{i=1}^n dx_i/x_i) \), we will show instead the equivalent statement that \( \hat{f} \) is in \( L^2_{\text{sym}}(i\mathbb{R}^n, s_n(\lambda) \, d\lambda) \). It is clear that \( \hat{f} \) is a symmetric function, and has no poles, thanks to the assumption that each \( \alpha_j \) has positive real part. Recalling the Stirling approximation of the Gamma function

\[
|\Gamma(x + iy)| \sim \sqrt{2\pi} |y|^{x - 1/2} e^{-\pi |y|} \quad \text{as} \quad |y| \to \infty ,
\]

we can compute the asymptotics of \( |\hat{f}(\lambda)|^2 s_n(\lambda) \) as \( |\lambda_i| \to \infty \) for all \( i \) and \( |\lambda_i - \lambda_j| \to \infty \) for all \( i < j \) (which is when \( s_n(\lambda) \) has the worst diverging behavior):

\[
|\hat{f}(\lambda)|^2 s_n(\lambda) = r^{-2\sum_{\alpha, \beta} \Re(\alpha), \beta} \prod_{i, j} \Gamma(\lambda_i + \alpha_j)^2 \left( \frac{2\pi)^n n! \prod_{i \neq j} \Gamma(\lambda_i - \lambda_j) \right) \sim \prod_{i < j} \frac{\exp\left( -\pi n \sum_i |\lambda_i| + \pi \sum_{i < j} |\lambda_i - \lambda_j| \right)}{\prod_{i < j} e^{-\pi |\lambda_i - \lambda_j|}}.
\]

Here, the symbol \( \sim \) denotes asymptotic behavior up to multiplicative constants and powers, and for the last step we have used the following rough estimate:

\[
\sum_{i < j} |\lambda_i + \lambda_j| \leq \sum_{i < j} (|\lambda_i| + |\lambda_j|) = (n - 1) \sum_i |\lambda_i| .
\]

This proves that \( |\hat{f}(\lambda)|^2 s_n(\lambda) \) is integrable on \( i\mathbb{R}^n \).

(b) Consider now \( g \) and \( \hat{g} \). The fact that the latter is indeed the \( gl_n \)-Whittaker transform of the former follows from property (2.7) and Ishii-Stade identity (2.15). Let us prove that \( \hat{g} \) belongs to \( L^2_{\text{sym}}(i\mathbb{R}^n, s_n(\lambda) \, d\lambda) \). Again, \( \hat{g} \) is a symmetric function, and has no poles, thanks to the assumption that \( \Re(s) > |\Re(\beta_j)| \) for all \( j \). Using (3.23) and (3.24), we compute the asymptotics (up to constants) of \( |\hat{g}(\lambda)|^2 s_n(\lambda) \) as \( |\lambda_i| \to \infty \) for all \( i \) and \( |\lambda_i \pm \lambda_j| \to \infty \) for
all $i < j$:  
\[ |\hat{g}(\lambda)|^2 s_n(\lambda) = \frac{\prod_{i \neq j} |(\lambda - \beta_i)(\lambda - \beta_j)|^2}{(2\pi)^n n! \prod_{i < j} |(2\lambda - \lambda_i - \lambda_j)|^2 \prod_{i,j} |\Gamma(\lambda - \lambda_j)|} \sim \prod_{i < j} e^{-2\pi|\lambda_i - \lambda_j|} \]
\[ = \exp \left( -2\pi n \sum_i |\lambda_i| + \pi \sum_{i < j} |\lambda_i + \lambda_j| + \pi \sum_{i < j} |\lambda_i - \lambda_j| \right) \leq \exp \left( -2\pi \sum_i |\lambda_i| \right), \]
which proves the integrability of $|\hat{g}(\lambda)|^2 s_n(\lambda)$ on $i\mathbb{R}^n$. □

**Theorem 3.15.** The Laplace transform of the point-to-line partition function $Z_{2n}$ for the $(\alpha, \beta, \gamma)$-log-gamma polymer is given by

\[
E \left[ e^{-rZ_{2n}^{\text{flat}}} \right] = \frac{\prod_{i=1}^n (\alpha_i + \beta_i)}{\Gamma_{\alpha,\beta,\gamma}} \int_{(\mathbb{R}^n)^n} s_n(\varrho) d\varrho \int_{(\mathbb{R}^n)^n} s_n(\lambda) d\lambda \left( -\sum_{i=1}^n (\lambda_i + \varepsilon_i + \gamma) \right) \]
\[
\times \prod_{1 \leq i,j \leq n} \frac{\Gamma(\lambda_i + \varrho_j + \gamma) \Gamma(\lambda_i + \alpha_j) \Gamma(\lambda_i - \alpha_j) \Gamma(\varrho_i + \beta_j) \Gamma(\varrho_i - \beta_j)}{\prod_{1 \leq i,j \leq n} \Gamma(\lambda_i + \lambda_j) \Gamma(\varrho_i + \varrho_j)}
\]

for all $r > 0$, where $\Gamma_{\alpha,\beta,\gamma}$ is the constant defined in (3.7), $s_n(\lambda) d\lambda$ is the Sklyanin measure as in (2.8) and $\delta, \varepsilon$ satisfy $\delta > \alpha_j$ and $\varepsilon > \beta_j$ for all $j$. The contour integral (3.25) is absolutely convergent.

**Proof.** We start from formula (3.10) and apply the $\mathfrak{gl}_n$-Whittaker-Plancherel Theorem 2.2 in a two-step procedure.

The integral appearing in formula (3.10) can be written as

\[
\int_{\mathbb{R}^n_+} \left( \prod_{i=1}^n x_i \right)^\gamma e^{-r x_1 \Psi_{\alpha}^{\delta_{2n+1}}(x)} \Psi_{\beta}^{\delta_{2n+1}}(x) \prod_{i=1}^n \frac{dx_i}{x_i} = \int_{\mathbb{R}^n_+} f(x) g(x) \prod_{i=1}^n \frac{dx_i}{x_i},
\]

where

\[
f(x) := \left( \prod_{i=1}^n x_i \right)^{\gamma + \varepsilon} e^{-r x_1 \Psi_{\alpha}^{\delta_{2n+1}}(x)}, \quad g(x) := \left( \prod_{i=1}^n x_i \right)^{-\varepsilon} \Psi_{\beta}^{\delta_{2n+1}}(x).
\]

By Lemma 3.14 since $\varepsilon > \beta_j > 0$ for all $j$, $g$ belongs to $L^2(\mathbb{R}^n_+, \prod_{i=1}^n dx_i/x_i)$ and satisfies

\[
\overline{g}(\varrho) = \prod_{1 \leq i,j \leq n} \frac{\Gamma(\varepsilon + \varrho_i + \beta_j) \Gamma(\varepsilon + \varrho_i - \beta_j)}{\prod_{1 \leq i,j \leq n} \Gamma(2\varepsilon + \varrho_i + \varrho_j)}
\]

for all $\varrho \in i\mathbb{R}^n$. On the other hand, applying Theorem 3.5 in the case where $\alpha = \beta, \gamma$ is replaced by $2(\gamma + \varepsilon)$ and $r$ is replaced by $2r$, we obtain that

\[
\int_{\mathbb{R}^n_+} |f(x)|^2 \prod_{i=1}^n \frac{dx_i}{x_i} = \frac{\Gamma_{\alpha,\alpha,2(\gamma+\varepsilon)}}{(2r)^2 \sum_{k=1}^n (\alpha_k+\gamma+\varepsilon)} E[|e^{-2rZ_{2n}}|] < \infty,
\]

(3.27)
where $\hat{Z}_{2n}^{\text{flat}}$ is the point-to-line partition function of the $(\alpha, \alpha, 2(\gamma + \varepsilon))$-log-gamma polymer. This proves that $f$ also belongs to $L^2(\mathbb{R}_+^n, \prod_{i=1}^n dx_i/x_i)$, so we can apply the $\mathfrak{gl}_n$-Whittaker-Plancherel theorem in (3.26) and obtain:
\[
\int_{\mathbb{R}_+^n} \left( \prod_{i=1}^n x_i \right)^\gamma e^{-rx_1} \Psi_{\alpha,\alpha}^{s_0n+1} (x) \Psi_{\beta}^{s_0n+1} (x) \prod_{i=1}^n \frac{dx_i}{x_i} = \int_{(\varepsilon+\mathbb{R})^n} f(\varepsilon - \varepsilon) \prod_{1 \leq i < j \leq n} \Gamma(\varrho_i + \beta_j) \Gamma(\varrho_i - \beta_j) \prod_{1 \leq i < j \leq n} \Gamma(\varrho_i + \varrho_j) \frac{d\varrho}{\varrho},
\]
(3.28)
after the change of variables $\varrho \rightarrow \varrho - \varepsilon$. To compute $\hat{f}(\varrho - \varepsilon)$, we first notice that by property (2.7)
\[
\hat{f}(\varrho - \varepsilon) = \int_{\mathbb{R}_+^n} \left( \prod_{i=1}^n x_i \right)^{\gamma+\varepsilon} e^{-rx_1} \Psi_{\alpha,\alpha}^{s_0n+1} (x) \Psi_{\beta}^{s_0n+1} (x) \prod_{i=1}^n \frac{dx_i}{x_i} = \int_{\mathbb{R}_+^n} \left[ e^{-rx_1} \Psi_{\alpha,\alpha}^{s_0n+1} (x) \right] \left[ \prod_{i=1}^n \frac{x_i}{x_i} \right] \prod_{i=1}^n \frac{dx_i}{x_i}.
\]
By Lemma 3.14 since $\gamma \geq 0$, $\delta > \alpha_j > 0$ and $\Re(\varrho_j) = \varepsilon$ for all $j$, the two functions in the square brackets belong to $L^2(\mathbb{R}_+^n, \prod_{i=1}^n dx_i/x_i)$, with $\mathfrak{gl}_n$-Whittaker transforms given by the same lemma. Applying the Plancherel theorem again, we then obtain
\[
\hat{f}(\varrho - \varepsilon) = \int_{(\varepsilon+\mathbb{R})^n} r^{-\sum_{i=1}^n (\lambda_i + \varrho_i + \gamma)} \prod_{1 \leq i < j \leq n} \Gamma(\lambda_i + \varrho_j + \gamma) \Gamma(\lambda_i + \alpha_j) \Gamma(\lambda_i - \alpha_j) \prod_{1 \leq i < j \leq n} \Gamma(\lambda_i + \lambda_j) \frac{d\lambda}{\lambda},
\]
after shifting the contour integral by $\delta$. Plugging the latter formula into (3.28) concludes the proof of (3.25).

Finally, we are going to show that the integral in (3.25) is absolutely convergent, so that the order of integration with respect to $\lambda$ and $\varrho$ does not matter. Note first that the integrand has no poles thanks to the choice of $\delta$ and $\varepsilon$. So we just need to check integrability as $|\Im(\lambda_i)|, |\Im(\varrho_i)| \to \infty$ for all $i$ and $|\Im(\lambda_i \pm \lambda_j)|, |\Im(\varrho_i \pm \varrho_j)| \to \infty$ for all $i < j$. Using the asymptotics of the Gamma function (3.23), it suffices to check the integrability of
\[
\prod_{i \neq j} e^{-\frac{1}{2} |\Im(\lambda_i + \varrho_j)|} e^{-\frac{1}{2} |\Im(\lambda_i + \lambda_j)|} e^{-\frac{1}{2} |\Im(\varrho_i + \varrho_j)|} \prod_{i \neq j} e^{-\frac{1}{2} |\Im(\lambda_i - \lambda_j)|} e^{-\frac{1}{2} |\Im(\varrho_i - \varrho_j)|}.
\]
Since we are looking at the regime of large imaginary parts for $\varrho$ an $\lambda$, we may assume that they are purely imaginary, hence we need to estimate
\[
- \sum_{i,j} (|\lambda_i + \varrho_j| + 2|\lambda_i| + 2|\varrho_i|) + \sum_{i < j} (|\lambda_i + \lambda_j| + |\varrho_i + \varrho_j|) + \sum_{i < j} (|\lambda_i - \lambda_j| + |\varrho_i - \varrho_j|). \quad (3.29)
\]
At this stage, since the imaginary $i$ will be absorbed by the absolute value, we may assume that $\lambda$ and $\varrho$ are real variables and, furthermore, since the above expression is symmetric, we may assume that
\[
\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n \quad \text{and} \quad \varrho_1 \leq \varrho_2 \leq \cdots \leq \varrho_n.
\]
This will then allow the bound
\[
\sum_{i \neq j} |(\lambda_i - \lambda_j) + (q_i - q_j)| = 2 \sum_{i < j} |(\lambda_i - \lambda_j) + (q_i - q_j)| = 2 \sum_{i \leq j} |(\lambda_i + q_j) - (q_i + \lambda_j)|
\]
\[
= \sum_{i,j} |(\lambda_i + q_j) - (q_i + \lambda_j)| \leq \sum_{i,j} |\lambda_i + q_j| + \sum_{i,j} |q_i + \lambda_j| = 2 \sum_{i,j} |\lambda_i + q_j|.
\]
Using the latter estimate and the one given in (3.24), we obtain
\[
(3.29) \leq - \sum_{i,j} (|\lambda_i + q_j| - 2n \sum_i (|\lambda_i| + |q_i|) + (n-1) \sum_i (|\lambda_i| + |q_i|) + 2 \sum_{i,j} |\lambda_i + q_j| = (-2n + n-1) \sum_i (|\lambda_i| + |q_i|) + \sum_{i,j} |\lambda_i + q_j| \leq (-n-1) \sum_i (|\lambda_i| + |q_i|) + n \sum_i |\lambda_i| + n \sum_j |q_j| = - \sum_i (|\lambda_i| + |q_i|),
\]
hence the exponential of (3.29) is integrable for \((\lambda, q) \in \mathbb{R}^{2n}\).

A contour integral formula for the point-to-half-line partition function is easier to obtain because it requires to apply the \(\mathfrak{gl}_n\)-Whittaker-Plancherel theorem only once.

**Theorem 3.16.** The Laplace transform of the point-to-half-line partition function \(Z_{2n}^{h\text{-flat}}\) for the \((\alpha, \beta)\)-log-gamma polymer is given by
\[
\mathbb{E} \left[ e^{-r Z_{2n}^{h\text{-flat}}} \right] = \frac{r^{\delta(n) + \delta(n)}}{\Gamma_{\alpha, \beta}^{h\text{-flat}}} \int_{(\delta+i\mathbb{R})^n} s_n(\lambda) \frac{d\lambda}{\prod_{1 \leq i < j \leq n} \Gamma(\lambda_i + \alpha_j) \Gamma(\lambda_i - \alpha_j) \Gamma(\lambda_i + \beta_j)} \],
\]
for all \(r > 0\), where \(\Gamma_{\alpha, \beta}^{h\text{-flat}}\) is the constant defined in (3.12), \(s_n(\lambda) \, d\lambda\) is the Sklyanin measure as in (2.8), and \(\delta\) is chosen such that \(\delta > \alpha_j\) for all \(j\).

**Proof.** It suffices to write the integral on the right-hand side of (3.15) as
\[
\int_{\mathbb{R}_+^n} e^{-rx_1} \Psi_{\alpha}^{\delta_0} (x) \Psi_{\beta}^{\delta_0} (x) \prod_{i=1}^n \frac{dx_i}{x_i} = \int_{\mathbb{R}_+^n} \left[ e^{-rx_1} \Psi_{\beta}^{\delta_0} (x) \right] \frac{d\lambda_1}{\prod_{i=1}^n \Gamma(\lambda_i + \alpha_j) \Gamma(\lambda_i - \alpha_j) \Gamma(\lambda_i + \beta_j)} \],
\]
where we multiplied and divided by \((\prod_{i=1}^n x_i)^\delta\) and used property (2.7). We now apply Theorem 2.2 to the two functions in the square brackets, whose \(\mathfrak{gl}_n\)-Whittaker-transforms have been computed in Lemma 3.14.

4. Zero Temperature Limit

In this section, we derive the zero temperature limit of the formulae provided by Theorems 3.5, 3.7 and 3.13 for the Laplace transforms of the flat, half-flat and restricted half-flat log-gamma polymer partition functions respectively, deriving what seem to be new formulae for the law of the last passage percolation with exponential waiting times in these three path geometries.
Let us first define, for a given triangular array \( W = \{ W_{i,j} : i + j \leq N + 1 \} \), the zero temperature analogue of (1.4), i.e. the point-to-line last passage percolation time:

\[
\tau_{\text{flat}}^{N} := \max_{\pi \in \Pi_{\text{flat}}^{N}} \sum_{(i,j) \in \pi} W_{i,j}.
\]

Similarly, the zero temperature analogues of (1.5) and (1.6) are the point-to-half-line and restricted point-to-half-line last passage percolation times:

\[
\tau_{\text{h-flat}}^{N} := \max_{\pi \in \Pi_{\text{h-flat}}^{N}} \sum_{(i,j) \in \pi} W_{i,j}, \quad \tau_{\text{r-flat}}^{N} := \max_{\pi \in \Pi_{\text{r-flat}}^{N}} \sum_{(i,j) \in \pi} W_{i,j}.
\]

The following technical proposition, whose proof is easy and omitted, explains how the zero temperature limit works. It is not specific to the log-gamma distribution.

**Proposition 4.1.** Let \( Z^{(\varepsilon)}_{N} \) be the polymer partition function corresponding to any of the path geometries considered, with disorder given by independent positive weights \( W^{(\varepsilon)}_{i,j} \), whose distributions depend on a parameter \( \varepsilon > 0 \). Let \( \tau_{N} \) be the last passage percolation in the same geometry, with independent positive continuous waiting times \( W = \{ W_{i,j} \} \).

Assuming that each \( \varepsilon \log W^{(\varepsilon)}_{i,j} \) converges in distribution to \( W_{i,j} \) as \( \varepsilon \downarrow 0 \), we have:

(i) \( \varepsilon \log Z^{(\varepsilon)}_{N} \xrightarrow{d} \varepsilon \downarrow 0 \tau_{N} \);

(ii) \( \mathbb{E} \left[ \exp \left( -u/\varepsilon Z^{(\varepsilon)}_{N} \right) \right] \xrightarrow{\varepsilon \downarrow 0} \mathbb{P}(\tau_{N} \leq u) \), for all \( u \in \mathbb{R} \).

On the other hand, it is easy to check that, if \( W^{(\varepsilon)} \) is inverse-gamma distributed with parameter \( \varepsilon \gamma \) and \( W \) is exponentially distributed with rate \( \gamma \) for some \( \gamma > 0 \), then

\[
\varepsilon \log W^{(\varepsilon)} \xrightarrow{d} \varepsilon \downarrow 0 W.
\]

Joining this observation to Proposition 4.1(ii) it is now clear how to recover the distribution of the last passage percolation with exponentially distributed waiting times from the rescaled Laplace transforms of the log-gamma polymer partition functions, in any of the three path geometries.

**4.1. The point-to-line last passage percolation.** In the zero temperature limit of the \((\varepsilon \alpha, \varepsilon \beta, 0)\)-log-gamma polymer partition function (refer to Definition 3.2 and set \( \gamma := 0 \)), we will be able to obtain the distribution of the point-to-line last passage percolation \( \tau_{2n}^{\text{flat}} \) with independent waiting times distributed as follows:

\[
W_{i,j} \sim \begin{cases} 
\text{Exp}(\alpha_{i} + \beta_{j}) & 1 \leq i, j \leq n, \\
\text{Exp}(\alpha_{i} + \alpha_{2n-j+1}) & 1 \leq i \leq n, n < j \leq 2n - i + 1, \\
\text{Exp}(\beta_{2n-i+1} + \beta_{j}) & 1 \leq j \leq n, n < i \leq 2n - j + 1.
\end{cases}
\] (4.1)
Baik and Rains \cite{BR01} derived the law of $\tau_N^{\flat}$ when $W_{i,j}$ are independent, geometrically distributed variables with parameters $1 - y_i y_{N+1-j}$. In particular, they established that

$$
P(\tau_N^{\flat} \leq u) = \prod_{1 \leq i \leq j \leq N} (1 - y_i y_j) \sum_{\mu \in \mathbb{Z}_+^N} s_{2\mu}(y_1, \ldots, y_N), \quad \text{(4.2)}$$

where $s_{2\mu}$ is the Schur polynomial with shape $2\mu$. Here, $\mathbb{Z}_+^N$ is the Schur polynomial with shape $\mu$.

The denominator can be expressed more explicitly \cite[24.17]{FH91}:

\[
\frac{\det (y_j^{\mu_i+n-i+1} - y_j^{-(\mu_i+n-i+1)})_{1 \leq i, j \leq n}}{\det (y_j^{n-i+1} - y_j^{-(n-i+1)})_{1 \leq i, j \leq n}}.
\]

The denominator can be expressed more explicitly \cite[24.17]{FH91}:

\[
\det (y_j^{n-i+1} - y_j^{-(n-i+1)})_{1 \leq i, j \leq n} = \prod_{1 \leq i < j \leq n} (y_i - y_j)(y_i y_j - 1) \prod_{i=1}^n (y_i^2 - 1) y_i^{-n}.
\]

We first prove a formula for the rescaled limit of orthogonal Whittaker functions: the proof relies on the fact that these can be approximated by symplectic Schur polynomials, which can in turn be expressed as a ratio of determinants by the Weyl character formula.

**Proposition 4.2.** Let $\alpha, x \in \mathbb{R}^n$ and let $\text{GT}_{2n}(x)$ be the set of symplectic Gelfand-Tsetlin patterns with shape $x$. We then have that

\[
\lim_{\epsilon \to 0} \epsilon^2 \Psi_{\epsilon x}^{\text{sp}_{2n+1}}(e^{x_1/\epsilon}, \ldots, e^{x_n/\epsilon}) = \text{sp}_{\alpha}^\text{cont}(x) \mathbb{1}_{\{0 \leq x_n \leq \cdots \leq x_1\}},
\]

where $\text{sp}_{\alpha}^\text{cont}(x)$ is the Schur polynomial with shape $\alpha q^n$.
where

\[ sp_{\alpha}^{\text{cont}}(x) := \int_{\mathbb{R}_{2n}} \prod_{k=1}^{n} e^{\alpha_k(2|z_{2k-1}| - |z_{2k-2}| - |z_{2k}|)} \prod_{1 \leq i < 2n \atop 1 \leq j \leq |i/2|} dz_{i,j} \]  

(4.5)

is a continuum version of the symplectic Schur function, and \( |z_i| := \sum_{j=1}^{[i/2]} z_{i,j} \). Moreover, \( sp_{\alpha}^{\text{cont}} \) has a determinantal form:

\[ sp_{\alpha}^{\text{cont}}(x) = \frac{\det(e^{\alpha_j x_i} - e^{\alpha_j x_i})_{1 \leq i,j \leq n}}{\prod_{1 \leq i < j \leq n}(\alpha_i - \alpha_j) \prod_{1 \leq i \leq j \leq n}(\alpha_i + \alpha_j)}. \]  

(4.6)

**Remark 4.3.** When \( \alpha_i = \alpha_j \) for some \( i, j \), (4.6) is still valid in the limit as \( \alpha_i - \alpha_j \to 0 \). In particular, when all \( \alpha_i \)'s are equal to a given \( \alpha \), we have that

\[ sp_{\alpha}^{\text{cont}}(x) = (-1)^n(n-1)/2 \frac{\det(x_i^{j-1}(e^{\alpha}x_i + (-1)^j e^{\alpha}x_i))_{1 \leq i,j \leq n}}{(2\alpha)^{n(n+1)/2} \prod_{j=1}^{n}(j-1)!}. \]

This formula is an immediate consequence of the following fact: if the functions \( f_1, \ldots, f_n \) are differentiable \( n - 1 \) times at \( \alpha \), then

\[ \frac{\det(f_i(\alpha_j))_{1 \leq i,j \leq n}}{\prod_{1 \leq i < j \leq n}(\alpha_i - \alpha_j)} \to \frac{W(f_1, \ldots, f_n)(\alpha)}{\prod_{j=1}^{n}(j-1)!} \]  

as \( \alpha_1, \ldots, \alpha_n \to \alpha \),

where \( W(f_1, \ldots, f_n)(\alpha) = \det(f_i^{(j)}(\alpha))_{1 \leq i,j \leq n} \) is the Wronskian at \( \alpha \).

**Proof.** In Definition 2.4, we change variables by setting \( z_{i,j} \mapsto e^{\alpha_j i/j} \) for all \( 1 \leq i < 2n \) and \( 1 \leq j \leq [i/2] \) and obtain

\[ \varepsilon^{n^2} \Psi_{\varepsilon}^{a \leftrightarrow 2n+1}(e^{x_1/\varepsilon}, \ldots, e^{x_n/\varepsilon}) = \int_{\mathbb{R}_{2n}} \prod_{k=1}^{n} \exp \left( \frac{2|z_{2k-1}|}{\varepsilon} - \frac{|z_{2k-2}|}{\varepsilon} - \frac{|z_{2k}|}{\varepsilon} \right) \prod_{1 \leq i < 2n \atop 1 \leq j \leq [i/2]} dz_{i,j}, \]

with the convention that \( z_{i,j} := 0 \) when \( j > [i/2] \). Since \( \exp(-e^{a-b}/\varepsilon) \xrightarrow{\varepsilon \downarrow 0} 1_{\{a \leq b\}} \) for all \( a \neq b \), we then have

\[ \prod_{i=1}^{2n-1} \prod_{j=1}^{[i/2]} \exp(-e^{z_{i+1,j+1}-z_{i,j}}/\varepsilon) \exp(-e^{z_{i,j}-z_{i+1,j}}/\varepsilon) \xrightarrow{\varepsilon \downarrow 0} 1_{\mathbb{G}_{2n}(\mathbb{R})} \left( \{0 \leq x_0 \leq \ldots \leq x_1\} \right) \]

for a.e. \( z \in \mathbb{G}_{2n}(\mathbb{R}) \). By dominated convergence, we thus obtain

\[ \lim_{\varepsilon \downarrow 0} \varepsilon^{n^2} \Psi_{\varepsilon}^{a \leftrightarrow 2n+1}(e^{x_1/\varepsilon}, \ldots, e^{x_n/\varepsilon}) = 1_{\{0 \leq x_0 \leq \ldots \leq x_1\}} \int_{\mathbb{G}_{2n}(\mathbb{R})} \prod_{k=1}^{n} e^{\alpha_k(2|z_{2k-1}| - |z_{2k-2}| - |z_{2k}|)} \prod_{1 \leq i < 2n \atop 1 \leq j \leq [i/2]} dz_{i,j}. \]
The latter integral is equal to the function \(\text{sp}_{\alpha}^{\text{cont}}(x)\) defined in (4.5). By Riemann sum approximation, we can rewrite it as

\[
\text{sp}_{\alpha}^{\text{cont}}(x) = \lim_{\delta \to 0} \sum_{x \in \mathbb{Z}^2} \delta^2 \prod_{k=1}^{n-1} e^{\delta \alpha_k (2|x_{2k-1}|-|x_{2k-2}|-|x_{2k}|)} e^{\delta \alpha_n (2|x_{2n-1}|-|x_{2n-2}|)-\alpha_n|x|}
\]

where \(\text{sp}_{\alpha}(x)\) is the symplectic Schur polynomial with shape \([\alpha]\). From the Weyl character formula (4.3) for \(\text{Sp}_{2n}\) we have:

\[
\text{sp}_{\alpha}(x) = \text{det} \left( e^{\delta \alpha_i (|x_i|+n-i+1)} - e^{-\delta \alpha_j (|x_j|+n-i+1)} \right)_{1 \leq i, j \leq n}
\]

\[
= \lim_{\delta \to 0} \frac{\delta^n}{\delta^n} \frac{\text{det} \left( e^{\delta \alpha_i x_i} - e^{-\delta \alpha_j x_j} \right)}{\delta^n \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j)(\alpha_i + \alpha_j) \prod_{i=1}^n (2\alpha_i)}
\]

Noting finally that \(e^{-\alpha_n|x|+\delta \alpha_n||x||} \rightarrow 1\), (4.6) follows.

**Theorem 4.4.** Let \(r_{\text{flat}}^{\text{flat}}\) be the point-to-line last passage percolation with exponentially distributed waiting times as in (4.1). Then, for all \(u > 0\):

\[
\mathbb{P}(r_{\text{flat}}^{\text{flat}} \leq u) = \frac{H_{\alpha, \beta}}{e^{\sum_{k=1}^n (\alpha_k + \beta_k)}} \int_{0 \leq x_1 \leq \cdots \leq x_n \leq u} \text{sp}_{\alpha}^{\text{cont}}(x) \text{sp}_{\beta}^{\text{cont}}(x) \prod_{i=1}^n dx_i,
\]

where the function \(\text{sp}_{\alpha}^{\text{cont}}\) is defined in (4.5), and

\[
H_{\alpha, \beta} := \prod_{1 \leq i \leq n} (\alpha_i + \beta_i)(\beta_i + \beta_j) \prod_{1 \leq i < j \leq n} (\alpha_i + \beta_j)
\]

is a normalizing factor. We can further write (4.7) in a determinantal form as

\[
\mathbb{P}(r_{\text{flat}}^{\text{flat}} \leq u) = \frac{1}{C_{\alpha, \beta}} \text{det} \left( e^{-u(\alpha_i + \beta_j)} \int_0^u (e^{\alpha_i x} - e^{-\alpha_i x})(e^{\beta_j x} - e^{-\beta_j x}) dx \right)_{1 \leq i, j \leq n},
\]

where \(C_{\alpha, \beta}\) is a Cauchy’s determinant:

\[
C_{\alpha, \beta} := \text{det} \left( \frac{1}{\alpha_i + \beta_j} \right)_{1 \leq i, j \leq n} = \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j)(\beta_i - \beta_j) \prod_{1 \leq i < j \leq n} (\alpha_i + \beta_j).
\]

**Proof.** By Proposition 4.1 we just need to compute \(\lim_{\epsilon \to 0} \mathbb{E} \exp \left( -u/\epsilon Z_{2n}^{(\epsilon)} \right)\), where \(Z_{2n}^{(\epsilon)}\) is the point-to-line \((\epsilon \alpha, \epsilon \beta, 0)\)-log-gamma polymer partition function. Formula (3.10) with \(\gamma = 0\) yields:

\[
\mathbb{E} \left[ \exp \left( -e^{-u/\epsilon} Z_{2n}^{(\epsilon)} \right) \right] = \frac{1}{\Gamma_{\epsilon \alpha, \epsilon \beta, 0}} \int_{\mathbb{R}^n_+} e^{-u/\epsilon} \psi_{\epsilon \alpha, \epsilon \beta, 0}^{(n+1)}(x) \prod_{i=1}^n dx_i.
\]
The integral can be rewritten, changing variables \( x_i \rightarrow e^{x_i/\varepsilon} \) for \( 1 \leq i \leq n \), as follows:

\[
\int_{\mathbb{R}^n} e^{-u/\varepsilon} \psi_{\varepsilon \alpha}^{502n+1}(x) \psi_{\varepsilon \beta}^{502n+1}(x) \prod_{i=1}^{n} \frac{dx_i}{x_i}
\]

\[
= \varepsilon^{-2n^2} \int_{\mathbb{R}^n} e^{-\varepsilon(x_1-u)/\varepsilon^2} \varepsilon^n \psi_{\varepsilon \alpha}^{502n+1}(x) \varepsilon^n \psi_{\varepsilon \beta}^{502n+1}(x) \prod_{i=1}^{n} \frac{dx_i}{\varepsilon}
\]

where the asymptotics follow from Proposition 4.2 and the fact that \( e^{-\varepsilon(x_1-u)/\varepsilon^2} \xrightarrow{\varepsilon \downarrow 0} 1 \{x_1 \leq u\} \) for all \( x_1 \neq u \). On the other hand, using the definition of \( \Gamma_{\varepsilon \alpha, \varepsilon \beta, 0}^{\text{flat}} \) given in (4.7) and the asymptotics of the Gamma function near 0, we have:

\[
\Gamma_{\varepsilon \alpha, \varepsilon \beta, 0}^{\text{flat}} = \prod_{1 \leq i, j \leq n} \Gamma(\varepsilon(\alpha_i + \alpha_j)) \prod_{1 \leq i, j \leq n} \Gamma(\varepsilon(\beta_i + \beta_j)) \prod_{1 \leq i, j \leq n} \frac{1}{(\alpha_i + \alpha_j)(\beta_i + \beta_j)}
\]

Thus, (4.7) easily follows from the combination of the foregoing formulae.

We now further elaborate (4.7) by making use of the determinantal formula (4.6):

\[
e^{\frac{1}{n}} \sum_{k=0}^{n} (\alpha_k + \beta_k) \prod_{i=1}^{n} (\tau_{2i} \leq u)
\]

\[
= \int_{\{0 \leq x_n \leq \cdots \leq x_1 \leq u\}} \frac{H_{\alpha, \beta}(e^{\alpha x_i} - e^{-\alpha x_i})}{\prod_{1 \leq i, j \leq n} (\alpha_i - \alpha_j)(\beta_i - \beta_j)} \prod_{1 \leq i, j \leq n} \prod_{i=1}^{n} dx_i
\]

\[
= \frac{1}{C_{\alpha, \beta} n!} \int_{[0,u]^n} \det(e^{\alpha x_i} - e^{-\alpha x_i}) \prod_{1 \leq i, j \leq n} \prod_{i=1}^{n} dx_i
\]

In the latter computation, we have used: the fact that, by the alternating property of the determinant, the integral over \( \{0 \leq x_n \leq \cdots \leq x_1 \leq u\} \) is invariant by applying any permutation to the variables \( x_i \)'s; the definition of \( H_{\alpha, \beta} \) and \( C_{\alpha, \beta} \); and the Cauchy-Binet identity (see e.g. [For10], ch. 3)). We now use the multilinearity of the determinant to finally obtain (4.8).

4.2. THE POINT-TO-HALF-LINE LAST PASSAGE PERCOLATION.

For the half-flat and restricted half-flat cases, we just state the final formulae and briefly outline their proofs.

Similarly to (4.4), properly rescaling a \( GL_n(\mathbb{R}) \)-Whittaker function yields the continuum version of a classical Schur function, which, thanks to the Weyl character formula for \( GL_n \), can also be written in a determinantal form:

\[
s_{\beta}^{\text{cont}}(x) = \frac{\det(e^{\beta_j x_i})}{\prod_{1 \leq i, j \leq n}(\beta_i - \beta_j)}.
\]

Again, when \( \beta_i = \beta_j \) for some \( i, j \), the latter formula should be viewed in the limit as \( \beta_i - \beta_j \rightarrow 0 \).
Following the same steps as in the flat case, one can express the law of $\tau_{2n}^{h\text{-flat}}$, with exponentially distributed waiting times, in terms of an integral of (the continuum version of) a symplectic Schur function and a classical Schur function. Using the Cauchy-Binet identity in the same fashion as in Theorem 4.4, one finally obtains:

**Theorem 4.5.** Let $\tau_{2n}^{h\text{-flat}}$ be the point-to-half-line last passage percolation with exponentially distributed waiting times as in (4.1). Then, for all $u > 0$:

$$
\mathbb{P}(\tau_{2n}^{h\text{-flat}} \leq u) = \frac{H_{\alpha,\beta}^{h\text{-flat}}}{e^{u \sum_{k=1}^{n} (\alpha_k + \beta_k)}} \int_{\{0 \leq x_n \leq \ldots \leq x_1 \leq u\}} s_{C}^{\text{cont}}(x) s_{C}^{\text{cont}}(x) \prod_{i=1}^{n} dx_i, \quad (4.11)
$$

where the functions $s_{C}^{\text{cont}}$ and $s_{C}^{\text{cont}}$ are defined in (4.5) and (4.10), and

$$
H_{\alpha,\beta}^{h\text{-flat}} := \prod_{1 \leq i,j \leq n} (\alpha_i + \alpha_j) \prod_{1 \leq i,j \leq n} (\alpha_i + \beta_j)
$$

is a normalizing factor. We can further write (4.11) in a determinantal form as

$$
\mathbb{P}(\tau_{2n}^{h\text{-flat}} \leq u) = \frac{1}{C_{\alpha,\beta}} \det \left( e^{-u(\alpha_i + \beta_j)} \int_{0}^{u} (e^{\alpha_i x} - e^{-\alpha_i x}) (e^{\beta_j x} - e^{-\beta_j x}) dx \right)_{1 \leq i,j \leq n}, \quad (4.12)
$$

where $C_{\alpha,\beta}$ is the Cauchy’s determinant defined in (4.9).

### 4.3. The Restricted Last Passage Percolation

Finally, let us consider the restricted half-flat case. Here, the waiting times are supposed to be independent and distributed as follows:

$$
W_{i,j} \sim \begin{cases} 
\text{Exp}(\alpha_i) & 1 \leq i = j \leq n, \\
\text{Exp}(\alpha_i + \alpha_j) & 1 \leq i < j \leq n, \\
\text{Exp}(\alpha_i + \alpha_{2n-j+1}) & 1 \leq i \leq n, \, n < j \leq 2n - i + 1.
\end{cases} \quad (4.13)
$$

**Theorem 4.6.** Let $\tau_{2n}^{r\text{-flat}}$ be the restricted point-to-half-line last passage percolation with exponentially distributed waiting times as in (4.13). Then, for all $u > 0$:

$$
\mathbb{P}(\tau_{2n}^{r\text{-flat}} \leq u) = \frac{H_{\alpha}^{r\text{-flat}}}{e^{u \sum_{k=1}^{n} \alpha_k}} \int_{\{0 \leq x_n \leq \ldots \leq x_1 \leq u\}} s_{C}^{\text{cont}}(x) \prod_{i=1}^{n} dx_i, \quad (4.14)
$$

where the function $s_{C}^{\text{cont}}$ is defined in (4.5), and

$$
H_{\alpha}^{r\text{-flat}} := \prod_{i=1}^{n} \alpha_i \prod_{1 \leq i,j \leq n} (\alpha_i + \alpha_j) \prod_{1 \leq i,j \leq n} (\alpha_i + \alpha_j)
$$

is a normalizing factor. We can further write (4.14) in a Pfaffian form as

$$
\mathbb{P}(\tau_{2n}^{r\text{-flat}} \leq u) = \frac{\text{Pf}(\Phi^{(n)})}{\text{Pf}(S^{(n)})}, \quad (4.15)
$$

where matrices $\Phi^{(n)}$ and $S^{(n)}$ are skew-symmetric of order $n$ or $n + 1$, according to whether $n$ is even or odd respectively, and are defined by

$$
\Phi^{(n)}_{i,j} := \begin{cases} 
\int_{0}^{u} \int_{0}^{u} \text{sgn}(y-x) \varphi_i(x) \varphi_j(y) \, dx \, dy & \text{for } 1 \leq i, j \leq n, \\
\int_{0}^{u} \varphi_i(x) \, dx & \text{for } 1 \leq i \leq n, \, j = n + 1; \, \text{if } n \text{ is odd},
\end{cases}
$$

and

$$
S^{(n)}_{i,j} := \begin{cases} 
\int_{0}^{u} \int_{0}^{u} \varphi_i(x) \varphi_j(y) \, dx \, dy & \text{for } 1 \leq i, j \leq n.
\end{cases}
$$
having set \( \varphi_j(x) := \alpha_j e^{-u\alpha_j} (e^{\alpha_j x} - e^{-\alpha_j x}) \) for \( 1 \leq j \leq n \), and

\[
S_{i,j}^{(n)} := \begin{cases} \frac{\alpha_j - \alpha_i}{\alpha_j + \alpha_i} & \text{for } 1 \leq i, j \leq n, \\ 1 & \text{for } 1 \leq i \leq n, j = n + 1; \text{if } n \text{ is odd}. \end{cases}
\]

The denominator \( \text{Pf}(S^{(n)}) \) in (4.15) is known as Schur Pfaffian and, no matter the parity of \( n \), it satisfies:

\[
\text{Pf}(S^{(n)}) = \prod_{1 \leq i < j \leq n} \frac{\alpha_j - \alpha_i}{\alpha_j + \alpha_i}. \tag{4.16}
\]

**Proof.** The proof of (4.14) follows the same steps as in the flat case. For the proof of (4.15), one first uses the determinantal form (4.6) of \( \text{sp}_{\alpha}^{\text{cont}} \) and formula (4.16) to show that

\[
\Pr(\tau_{2n}^{\text{flat}} \leq u) = \frac{1}{\text{Pf}(S^{(n)})} \int_{\{0 \leq x_1 \leq \cdots \leq x_n \leq u\}} \det(\varphi_j(x_i))_{1 \leq i \leq j \leq n} \prod_{i=1}^{n} dx_i,
\]

where \( \varphi_j(x) := \alpha_j e^{-u\alpha_j} (e^{\alpha_j x} - e^{-\alpha_j x}) \) for \( 1 \leq j \leq n \). To see that the latter integral is indeed the desired Pfaffian, it suffices to use the following integral identity due to de Bruijn [Bru55]:

\[
\int_{\{x_1 \leq \cdots \leq x_n\}} \det(\varphi_j(x_i))_{1 \leq i \leq j \leq n} \prod_{i=1}^{n} \nu(dx_i) = \text{Pf}(\Phi^{(n)}),
\]

where \( \Phi^{(n)} \) is a skew-symmetric matrix of order \( n \) or \( n + 1 \), according to whether \( n \) is even or odd respectively, and is defined by

\[
\Phi^{(n)}_{i,j} := \begin{cases} \int_{\mathbb{R}^2} \text{sgn}(y-x) \varphi_i(x) \varphi_j(y) \nu(dx) \nu(dy) & \text{for } 1 \leq i, j \leq n, \\ \int_{\mathbb{R}} \varphi_i(x) \nu(dx) & \text{for } 1 \leq i \leq n, j = n + 1; \text{if } n \text{ is odd}. \end{cases}
\]

**Appendix A.**

The integral parametrization for Whittaker functions used in number theory and in by particular by [IS13] is different than ours: in this subsection, we will explain their connection and then show the equivalence between (2.15) and the corresponding integral formulae in [IS13]. As it will become clear, in both the \( \mathfrak{gl}_n \) and the \( \mathfrak{so}_{2n+1} \) cases the two parametrizations are linked via the change of variables

\[
y_1 := \frac{1}{\pi} \sqrt{\frac{x_2}{x_1}}, \quad \ldots, \quad y_{n-1} := \frac{1}{\pi} \sqrt{\frac{x_n}{x_{n-1}}}, \quad y_n := \frac{1}{\pi} \sqrt{\frac{1}{X_n}}. \tag{A.1}
\]

For \( \mathbf{a} \in \mathbb{C}^n \), set \( |\mathbf{a}| := a_1 + \cdots + a_n \). The \( \mathfrak{gl}_n \)-Whittaker function \( \hat{W}_{\alpha}^{A}_{\mathbf{n}, \mathbf{a}} \) indexed by \( \mathbf{a} \in \mathbb{C}^n \), according to the integral representation [IS13 Prop. 1.2], is defined as follows. For \( n = 2 \),

\[
\hat{W}_{2, (a_1, a_2)}^{A}(y_1, y_2) := 2 |\mathbf{a}|^{1/2} |\mathbf{y}|^{a_1-a_2} (2\pi y_1), \tag{A.2}
\]

\footnotemark

\footnotetext[1]{In this setting, we strictly stick to the notation of [IS13]. Accordingly, we remark that the hat in \( \hat{W}_{\alpha}^{A} \) and \( \hat{W}_{\alpha}^{B} \) do not denote any transform here.}
where $K$ is the Macdonald function
\[ K_{y}(x) := \frac{1}{2} \int_{R_{+}} z^{y} \exp \left( - \frac{x}{2} \left( z + \frac{1}{z} \right) \right) \frac{dz}{z}. \] (A.3)

Recursively, for all $n \geq 3$,
\[ \widehat{W}_{n, \alpha}(y) := \pi^{-|\alpha|/2} \int_{R^{n-1}_{+}} \widehat{W}_{n-1, \alpha} \left( y_{2} \sqrt{\frac{t_{2}}{t_{1}}}, \ldots, y_{n-1} \sqrt{\frac{t_{n-1}}{t_{n-2}}}, y_{n} \sqrt{\frac{1}{t_{n-1}}} \right) \times \prod_{j=1}^{n-1} \exp \left( - \frac{(\pi y_{j})^{2} t_{j}}{t_{j}} \right) \frac{dt_{j}}{t_{j}}, \] (A.4)

where $\alpha = (\alpha_{1}, \ldots, \alpha_{n-1})$ is defined by $\alpha_{i} := a_{i+1} + \frac{a_{i}}{n-1}$.

**Proposition A.1.** If $a_{i} = 2\alpha_{n-i+1}$ for $1 \leq i \leq n$, and $x$ and $y$ satisfy (A.1), then
\[ \widehat{W}_{n, \alpha}(y) = \pi^{-(n+1)|\alpha|} \Psi_{-\alpha}(x). \]

**Proof.** For $n = 2$, eq. (A.2) and the relations defining $y$ and $\alpha$ in terms of $x$ and $\alpha$ yield
\[ \widehat{W}_{2, (\alpha_{1}, \alpha_{2})}(y_{1}, y_{2}) = 2\pi^{-3|\alpha|} (x_{1}x_{2})^{-|\alpha|/2} K_{\alpha_{2}-\alpha_{1}} \left( 2 \frac{x_{2}}{x_{1}} \right). \]

On the other hand, (2.5) and (A.3) yield
\[ \Psi_{-\alpha_{1}-\alpha_{2}}(x_{1}, x_{2}) = 2(x_{1}x_{2})^{-|\alpha|/2} K_{\alpha_{2}-\alpha_{1}} \left( 2 \frac{x_{2}}{x_{1}} \right), \]

proving the desired identity for $n = 2$. Assume now that the result holds for $n - 1$. In light of (A.1) and after the change of variables $u_{j} = t_{j}x_{j+1}$ for $1 \leq j \leq n - 1$ in the integral (A.4), we obtain
\[ \widehat{W}_{n, \alpha}(y) = \pi^{-|\alpha|/2} \int_{R^{n-1}_{+}} \widehat{W}_{n-1, \alpha} \left( \frac{1}{\pi} \sqrt{\frac{u_{2}}{u_{1}}}, \ldots, \frac{1}{\pi} \sqrt{\frac{u_{n-1}}{u_{n-2}}}, \frac{1}{\pi} \sqrt{\frac{1}{u_{n-1}}} \right) \times \prod_{i=1}^{n} x_{i}^{-1} \prod_{j=1}^{n-1} \exp \left( - \frac{u_{j}}{x_{j}} - \frac{x_{j+1}}{u_{j}} \right) \frac{du_{j}}{u_{j}}. \]

Using the induction hypothesis and the property stated in (2.7), it is easy to see that
\[ \widehat{W}_{n-1, \alpha} \left( \frac{1}{\pi} \sqrt{\frac{u_{2}}{u_{1}}}, \ldots, \frac{1}{\pi} \sqrt{\frac{u_{n-1}}{u_{n-2}}}, \frac{1}{\pi} \sqrt{\frac{1}{u_{n-1}}} \right) = \pi^{-n|\alpha|} \left( \prod_{j=1}^{n} u_{j} \right)^{-\alpha_{n-1}} \Psi_{-\alpha_{1}-\ldots-\alpha_{n-1}}(u). \]

It follows that
\[ \widehat{W}_{n, \alpha}(y_{1}, \ldots, y_{n}) = \pi^{-(n+1)|\alpha|} \int_{R^{n-1}_{+}} \Psi_{-\alpha_{1}-\ldots-\alpha_{n-1}}(u) \times \left( \prod_{i=1}^{n} x_{i} \right)^{-\alpha_{n-1}} \prod_{j=1}^{n-1} \exp \left( - \frac{u_{j}}{x_{j}} - \frac{x_{j+1}}{u_{j}} \right) \frac{du_{j}}{u_{j}}. \]

Using the recursive relation (2.6), we get the desired identity for $n$. \qed
The $\mathfrak{so}_{2n+1}$-Whittaker function $\tilde{W}_{n,b}$ indexed by $b \in \mathbb{C}^n$, according to the integral representation [IS13, Prop. 1.3], is defined as follows. For $n = 1$,

$$
\tilde{W}_{1,b_1}^B(y_1) := 2K_{b_1}(2\pi y_1).
$$

(A.5)

Recursively, for all $n \geq 2$,

$$
\tilde{W}_{n,b}^B(y) := \int_{\mathbb{R}_+^n} \int_{\mathbb{R}_+^{n-1}} \tilde{W}_{n-1,b}^B \left( y_2 \sqrt{t_2s_2}, \ldots, y_{n-1} \sqrt{t_{n-1}s_{n-1}}, y_n \sqrt{t_n s_n} \right) \times \prod_{j=1}^{n-1} \exp \left( - (\pi y_j)^2 \frac{t_j}{t_{j+1}} s_j - \frac{1}{s_j} \right) \left( t_{j+1}s_j \right)^{\frac{b_n}{s_j}} ds_j \times \prod_{j=1}^n t_j^n \prod_{j=1}^n \exp \left( - (\pi y_j)^2 \frac{t_j}{t_{j+1}} \right) (\pi y_j)^{b_j} \frac{dt_j}{t_j},
$$

(A.6)

where $\tilde{b} = (b_1, \ldots, b_{n-1})$.

**Proposition A.2.** If $b_i = 2\beta_i$ for $1 \leq i \leq n$, and $x, y$ satisfy (A.1), then

$$
\tilde{W}_{n,b}^B(y) = \Psi_{\beta}^{\mathfrak{so}_{2n+1}}(x).
$$

**Proof.** For $n = 1$, we have indeed

$$
\tilde{W}_{1,b_1}^B(y_1) = 2K_{2\beta_1} \left( \frac{2}{\sqrt{x_1}} \right) = \Psi_{\beta_1}^{\mathfrak{so}_2}(x_1).
$$

Here, the first equality follows from (A.5) and the relations defining $y$ and $b$ in terms of $x$ and $\beta$, whereas the second equality is deduced by combining (2.13) and (A.3).

Assume now that the result holds for $n - 1$. In light of (A.1) and after the changes of variables $v_j = x_j/t_j$ for $1 \leq j \leq n$ and $u_j = v_{j+1}s_j$ for $1 \leq j \leq n - 1$ in the integral (A.6), we obtain

$$
\tilde{W}_{n,b}^B(y) = \int_{\mathbb{R}_+^n} \int_{\mathbb{R}_+^{n-1}} \tilde{W}_{n-1,b}^B \left( \frac{1}{\pi} \sqrt{u_1}, \ldots, \frac{1}{\pi} \sqrt{u_{n-2}}, \frac{1}{\pi} \sqrt{u_{n-1}} \right) \left( \prod_{j=1}^{n} u_j^{2} \prod_{j=1}^{n-1} x_j \prod_{j=1}^{n} \right) \left( \prod_{j=1}^{n} v_j \right)^{-\frac{b_n}{s_n}} \times \prod_{j=1}^{n-1} \exp \left( - \frac{u_j}{v_j} - \frac{v_{j+1}}{u_j} \right) du_j \prod_{j=1}^{n} \exp \left( - \frac{x_{j+1}}{v_j} - \frac{v_j}{x_j} \right) dv_j.
$$

Using the induction hypothesis and the fact that $b = 2\beta$, we see that the latter expression coincides with $\Psi_{\beta_1, \beta_2, \ldots, \beta_{n-1}, -\beta_n}^{\mathfrak{so}_{2n+1}}(x)$ (see recursive formula (2.14)), which in turn equals $\Psi_{\beta}^{\mathfrak{so}_{2n+1}}(x)$ due to the invariance of the Whittaker functions under the action of the Weyl group on the parameters $(\beta_1, \ldots, \beta_n)$; in this situation this amounts to invariance under permutations and multiplication by $\pm 1$. \hfill \square

Now, the integral formula we are interested in is stated in [IS13, Thm. 3.2]:

$$
2^n \int_{\mathbb{R}_+^n} \left( \prod_{j=1}^{n} y_j \right)^s \tilde{W}_{n,a}^A(y) \tilde{W}_{n,b}^B(y) \prod_{j=1}^{n} dy_j y_j = \prod_{1 \leq i, j \leq n} \Gamma_R(s + a_i + b_j) \Gamma_R(s + a_i - b_j) \prod_{1 \leq i < j \leq n} \Gamma_R(2s + a_i + a_j),
$$

where $\tilde{W}_{n,a}^A(y)$ and $\tilde{W}_{n,b}^B(y)$ are the $\mathfrak{so}_{2n+1}$-Whittaker functions indexed by $a \in \mathbb{C}^n$ and $b \in \mathbb{C}^n$, respectively.
where \( \Gamma_R(z) := \pi^{-z/2} \Gamma(z/2) \). Using the change of variables (A.1) and Propositions A.1 and A.2, the above formula can be easily rewritten as
\[
\int_{\mathbb{R}^n_+} \left( \prod_{i=1}^n x_i \right)^{-s/2} \Psi_{\gamma_n}^\alpha(x) \prod_{i=1}^n x_i \prod_{1 \leq i, j \leq n, i \neq j} \Gamma(s/2 + \alpha_i + \beta_j) \Gamma(s/2 + \alpha_i - \beta_j) \prod_{1 \leq i, j \leq n} \Gamma(s + \alpha_i + \alpha_j) \ .
\]
Theorem 2.5 now follows by taking \( s = 0 \). Note that, in turn, the latter identity can be deduced by Theorem 2.5, indeed, the term \( \left( \prod_{i=1}^n x_i \right)^{-s/2} \Psi_{\gamma_n}^\alpha(x) \) is itself a \( \mathfrak{gl}_n \)-Whittaker function as a whole, because of (2.7).

**Acknowledgements:** We would like to express our gratitude to T. Ishii and E. Stade for the many communications and explanations on their work and on Whittaker functions, including the relation between orthogonal Whittaker functions and symplectic Schur functions via the Casselman-Shalika formula, mentioned in the introduction. We also thank I. Nteka for useful discussions. NZ thanks Y. Sakellaridis for several long and very useful discussions. The work of NZ was supported by EPSRC via grant EP/L012154/1. The work of EB was supported by EPSRC via grant EP/M506679/1.
