ABSTRACT

Background
Coronary heart disease (CHD) is the most common cause of death globally. However, with falling CHD mortality rates, an increasing number of people living with CHD may need support to manage their symptoms and prognosis. Exercise-based cardiac rehabilitation (CR) aims to improve the health and outcomes of people with CHD. This is an update of a Cochrane Review previously published in 2016.

Objectives
To assess the clinical effectiveness and cost-effectiveness of exercise-based CR (exercise training alone or in combination with psychosocial or educational interventions) compared with 'no exercise' control, on mortality, morbidity and health-related quality of life (HRQoL) in people with CHD.

Search methods
We updated searches from the previous Cochrane Review, by searching CENTRAL, MEDLINE, Embase, and two other databases in September 2020. We also searched two clinical trials registers in June 2021.

Selection criteria
We included randomised controlled trials (RCTs) of exercise-based interventions with at least six months' follow-up, compared with 'no exercise' control. The study population comprised adult men and women who have had a myocardial infarction (MI), coronary artery bypass graft (CABG) or percutaneous coronary intervention (PCI), or have angina pectoris, or coronary artery disease.

Data collection and analysis
We screened all identified references, extracted data and assessed risk of bias according to Cochrane methods. We stratified meta-analysis by duration of follow-up: short-term (6 to 12 months); medium-term (> 12 to 36 months); and long-term (> 3 years), and used meta-regression to explore potential treatment effect modifiers. We used GRADE for primary outcomes at 6 to 12 months (the most common follow-up time point).
Main results

This review included 85 trials which randomised 23,430 people with CHD. This latest update identified 22 new trials (7795 participants). The population included predominantly post-MI and post-revascularisation patients, with a mean age ranging from 47 to 77 years.

In the last decade, the median percentage of women with CHD has increased from 11% to 17%, but females still account for a similarly small percentage of participants recruited overall (< 15%). Twenty-one of the included trials were performed in low- and middle-income countries (LMICs). Overall trial reporting was poor, although there was evidence of an improvement in quality over the last decade. The median longest follow-up time was 12 months (range 6 months to 19 years).

At short-term follow-up (6 to 12 months), exercise-based CR likely results in a slight reduction in all-cause mortality (risk ratio (RR) 0.87, 95% confidence interval (CI) 0.73 to 1.04; 25 trials; moderate certainty evidence), a large reduction in MI (RR 0.72, 95% CI 0.55 to 0.93; 22 trials; moderate certainty evidence), and a large reduction in all-cause hospitalisation (RR 0.58, 95% CI 0.43 to 0.77; 14 trials; moderate certainty evidence). Exercise-based CR likely results in little to no difference in risk of cardiovascular mortality (RR 0.88, 95% CI 0.68 to 1.14; 15 trials; moderate certainty evidence), CABG (RR 0.99, 95% CI 0.78 to 1.27; 20 trials; high certainty evidence), and PCI (RR 0.86, 95% CI 0.63 to 1.19; 13 trials; moderate certainty evidence) up to 12 months’ follow-up. We are uncertain about the effects of exercise-based CR on cardiovascular hospitalisation, with a wide confidence interval including considerable benefit as well as harm (RR 0.80, 95% CI 0.41 to 1.59; low certainty evidence). There was evidence of substantial heterogeneity across trials for cardiovascular hospitalisations (I² = 53%), and of small study bias for all-cause hospitalisation, but not for all other outcomes.

At medium-term follow-up, although there may be little to no difference in all-cause mortality (RR 0.90, 95% CI 0.80 to 1.02; 15 trials), MI (RR 1.07, 95% CI 0.91 to 1.27; 12 trials), PCI (RR 0.96, 95% CI 0.69 to 1.35; 6 trials), CABG (RR 0.97, 95% CI 0.77 to 1.23; 9 trials), and all-cause hospitalisation (RR 0.92, 95% CI 0.82 to 1.03; 9 trials), a large reduction in cardiovascular mortality was found (RR 0.77, 95% CI 0.63 to 0.93; 5 trials). Evidence is uncertain for difference in risk of cardiovascular hospitalisation (RR 0.92, 95% CI 0.76 to 1.12; 3 trials).

At long-term follow-up, although there may be little to no difference in all-cause mortality (RR 0.91, 95% CI 0.75 to 1.10), exercise-based CR may result in a large reduction in cardiovascular mortality (RR 0.58, 95% CI 0.43 to 0.78; 8 trials) and MI (RR 0.67, 95% CI 0.50 to 0.90; 10 trials). Evidence is uncertain for CABG (RR 0.66, 95% CI 0.34 to 1.27; 4 trials), and PCI (RR 0.76, 95% CI 0.48 to 1.20; 3 trials).

Meta-regression showed benefits in outcomes were independent of CHD case mix, type of CR, exercise dose, follow-up length, publication year, CR setting, study location, sample size or risk of bias.

There was evidence that exercise-based CR may slightly increase HRQoL across several subscales (SF-36 mental component, physical functioning, physical performance, general health, vitality, social functioning and mental health scores) up to 12 months’ follow-up; however, these may not be clinically important differences. The eight trial-based economic evaluation studies showed exercise-based CR to be a potentially cost-effective use of resources in terms of gain in quality-adjusted life years (QALYs).

Authors’ conclusions

This updated Cochrane Review supports the conclusions of the previous version, that exercise-based CR provides important benefits to people with CHD, including reduced risk of MI, a likely small reduction in all-cause mortality, and a large reduction in all-cause hospitalisation, along with associated healthcare costs, and improved HRQoL up to 12 months’ follow-up. Over longer-term follow-up, benefits may include reductions in cardiovascular mortality and MI. In the last decade, trials were more likely to include females, and be undertaken in LMICs, increasing the generalisability of findings. Well-designed, adequately-reported RCTs of CR in people with CHD more representative of usual clinical practice are still needed. Trials should explicitly report clinical outcomes, including mortality and hospital admissions, and include validated HRQoL outcome measures, especially over longer-term follow-up, and assess costs and cost-effectiveness.

Plain Language Summary

Exercise-based rehabilitation for coronary heart disease

Background

Coronary heart disease (CHD) is the single most common cause of death globally. However, with falling CHD mortality rates, an increasing number of people live with CHD and may need support to manage their symptoms (such as angina, shortness of breath with physical activity, and fatigue) and reduce the chances of future problems, such as heart attacks. Exercise-based cardiac rehabilitation (exercise training alone or in combination with psychological or educational interventions) aims to improve the health and outcomes of people with CHD.

Study characteristics
We searched the scientific literature for randomised controlled trials (experiments that randomly allocate participants to one of two or more treatment groups) looking at the effectiveness of exercise-based treatments compared with no exercise in people of all ages with CHD. The evidence is current to September 2020.

**Key results**
This latest update identified an additional 22 trials (7795 participants). We included a total of 85 trials that studied 23,430 people with CHD, predominantly heart attack survivors and those who had undergone heart bypass surgery or angioplasty (a procedure which widens narrowed or obstructed arteries or veins). Thirty-eight (45%) of the trials involved exercise-only interventions and 47 (55%) involved interventions with exercise plus other components. The type of exercise most often included was stationary cycling, walking or circuit training. Twenty-one (25%) of the interventions were delivered in the participants’ homes.

The findings of this update are consistent with the previous (2016) version of this Cochrane Review, and show important benefits of exercise-based cardiac rehabilitation that include a reduction in the risk of death due to any cause, heart attack, and hospital admission, and improvements in health-related quality of life, compared with not undertaking exercise. A small body of economic evidence was identified, indicating exercise-based cardiac rehabilitation to be cost-effective. Many of the studies identified in this current update were undertaken in low- and middle-income countries, which increases the generalisability of our results to these settings where levels of CHD are high and continue to increase.

**Quality of evidence**
Although the reporting of methods has improved in recent trials, lack of reporting key methodological aspects made it difficult to assess the overall methodological quality and risk of possible bias of the evidence.
### SUMMARY OF FINDINGS

**Summary of findings 1. Exercise-based cardiac rehabilitation compared to 'no exercise' control for coronary heart disease**

<sup>a</sup>The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

<sup>b</sup>P < 0.05 in the Egger test, and funnel plot asymmetry; therefore, downgraded by one level for suspected publication bias.

<sup>c</sup>Evidence of heterogeneity in the I² test; therefore, downgraded by one level for substantial heterogeneity.

CI: confidence interval; RR: risk ratio; OR: odds ratio; NNTB/H: number needed to treat for an additional beneficial/harmful outcome

**GRADE Working Group grades of evidence**

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.
BACKGROUND

Description of the condition

Coronary heart disease (CHD, see Glossary in Appendix 1) is the single most common cause of death globally, with 7.46 million deaths in 2016, accounting for one-third of all deaths (WHO 2018). In the United Kingdom (UK), an estimated 2.3 million people live with CHD – around 1.5 million men and 830,000 women, and the condition accounts for one in seven deaths in men and one in twelve deaths in women (BHF 2020). Although remaining stubbornly constant in low- and middle-income countries, the mortality rate from CHD has been falling in the UK and other high-income settings. This is due to factors such as declines in cigarette smoking, improvements in hypertension treatment and control, widespread use of statins to lower circulating cholesterol levels, and the development and timely use of thrombolysis and stents in acute coronary syndromes (Mensah 2017). Accordingly, an increasingly large number of people live with CHD and may need support to manage their symptoms and prognosis.

Description of the intervention

Many definitions of cardiac rehabilitation (CR) have been proposed. The following definition encompasses the key concepts of CR: “the coordinated sum of activities required to influence favourably the underlying cause of cardiovascular disease, as well as to provide the best possible physical, mental and social conditions, so that the patients may, by their own efforts, preserve or resume optimal functioning in their community and through improved health behaviour, slow or reverse progression of disease” (BACPR 2017). CR is a complex intervention that may involve a variety of therapies, including exercise, risk factor education, behaviour change, psychological support, and strategies that are aimed at targeting traditional risk factors for cardiovascular disease. CR is an essential part of contemporary CHD care and is considered a priority in countries with a high prevalence of CHD. Based on evidence - including from the previous version of this Cochrane Review (Anderson 2016) - CR following a cardiac event is a Class I recommendation from the European Society of Cardiology, and the American Heart Association and American College of Cardiology, with exercise therapy consistently identified as a central element (Knuuti 2020; Smith 2011). However, despite these positive recommendations for exercise-based CR, it continues to be widely underused with overall participation rates in recent decades of about 40% (Kotseva 2018). Service provision, though predominantly hospital-based, varies markedly, and referral, enrolment and completion are sub-optimal, especially amongst women and older people (Peters 2017; Ruano-Ravina 2016). Home- and technology-based CR programmes have been advocated to widen access and participation (Dalal 2015), and interventions aimed at improving patients’ uptake and adherence to CR programmes have been identified (Santiago de Araújo Pio 2019).

Exercise-based CR appears to be a safe intervention. An observational study of more than 25,000 people undergoing CR reported one cardiac event for 50,000 hours of exercise training, equivalent to 1.3 cardiac arrests per million patient-hours (Pavy 2006). An earlier study reported one case of ventricular fibrillation per 111,996 patient-hours of exercise, and one myocardial infarction (MI) per 294,118 patient-hours (Van Camp 1986). In the context of CR, higher risk CHD populations have been defined as those with severe in-hospital complications after acute coronary syndrome (ACS), cardiac surgery, or percutaneous coronary intervention (PCI) (Pelliccia 2020; Piepoli 2010).

How the intervention might work

Exercise training has been shown to have direct benefits on the heart and coronary vasculature, including myocardial oxygen demand, endothelial function, autonomic tone, coagulation and clotting factors, inflammatory markers, and the development of coronary collateral vessels (Clausen 1976; Hambrecht 2000). However, findings of the original Cochrane Review of exercise-based CR for CHD (Jolliffe 2001), supported the hypothesis that reductions in mortality may also be mediated via the indirect effects of exercise through improvements in atherosclerotic risk factors (i.e. lipids, smoking and blood pressure) (Taylor 2006).

Why it is important to do this review

People who have had acute MI and coronary revascularisation (along with heart failure) remain those most frequently recommended for CR referral by healthcare systems across the world (Piepoli 2010; Pelliccia 2020). Regular updates to this systematic review of randomised controlled trials (RCTs) of CR for CHD is therefore key to ensuring the contemporary nature of the evidence base in order to continue to inform healthcare policy makers and guideline producers.

The 2016 Cochrane review made the following two key recommendations for future evidence collection and clinical trials (Anderson 2016).

- The need for further evidence from ‘hard to reach’ groups, including women, elderly people, and ethnic minorities.
- The need for more consistent collection and reporting of validated health-related quality of life (HRQoL) outcomes, costs and cost-effectiveness.

In addition, the majority of evidence (58/63, 92%) in Anderson 2016 was collected in high-income countries (HICs), with a need to consider trials from low- and middle-income countries (LMICs) when they become available.

OBJECTIVES

To assess the clinical effectiveness and cost-effectiveness of exercise-based CR (exercise training alone or in combination with psychosocial or educational interventions) compared with ‘no exercise’ control, on mortality, morbidity and health-related quality of life (HRQoL) in people with CHD.

METHODS

Criteria for considering studies for this review

Types of studies

We included RCTs (with individual participant or cluster allocation, or cross-over design) and quasi-RCTs (RCTs in which treatment allocation was obtained by alternation or other predictable methods) of exercise-based CR versus ‘no exercise’ control. In order to present outcome data that are meaningful and relevant for clinical and policy decision-making, we limited our search to studies with a follow-up period of at least six months in our 2011 update of this Cochrane Review and subsequent updates.
Where a full text was not available, we contacted the study authors and attempted to collect further information. If we received no response, we placed the study into the 'awaiting classification' category.

**Types of participants**

We included adult (≥ 18 years) men and women, in either hospital-based and community-based settings, who have had a myocardial infarction (MI), or who have undergone revascularisation (CABG, PCI) or who have angina pectoris or coronary artery disease defined by angiography. We included trials with mixed indication population as long as more than 50% of the trial participants had a CHD diagnosis. Please note that the terms CHD and coronary artery disease (CAD) are (or can be) sometimes used interchangeably and terms are presented as described by trialists in the Characteristics of included studies.

We excluded studies which only included participants following heart valve surgery, with heart failure, atrial fibrillation or heart transplants, or implanted with either cardiac-resynchronisation therapy or implantable cardiovertor defibrillators. These indications are the subject of other Cochrane reviews (Anderson 2017; Nielsen 2019; Risom 2017; Sibitz 2016; Long 2019). We also excluded studies of participants who had completed a CR programme prior to randomisation.

**Types of interventions**

Exercise-based CR is defined as a supervised or unsupervised inpatient, outpatient, community- or home-based intervention which includes some form of exercise training that is applied to a cardiac patient population. The intervention could be exercise training alone or exercise training in addition to psychosocial or educational interventions, or both (i.e. "comprehensive CR"). All CR interventions were compared to a 'no exercise' control, and both the intervention and control group received usual medical care. Usual care could include standard medical care, such as drug therapy, but without any form of structured exercise training or advice.

**Types of outcome measures**

Studies should have intended to assess any of the following outcomes in both the CR and the control groups, but these outcomes did not form the basis of our inclusion/exclusion criteria. We collected outcome data at three follow-up periods: short-term (6 to 12 months), medium-term (> 12 to 36 months), and long-term (> than 36 months).

**Primary outcomes**

- All-cause mortality
- Cardiovascular mortality
- Fatal MI and/or non-fatal MI
- Revascularisation with CABG
- Revascularisation with PCI
- All-cause hospitalisation
- Cardiovascular hospitalisation

We sought data on the number of trial participants who experienced the above events.

**Secondary outcomes**

- HRQoL assessed using validated instruments (e.g. SF-36 (a 36-item Short Form Health Survey); or EQ-5D (a standardised measure developed by the EuroQol Group))
- Costs and cost-effectiveness - we sought reports of total healthcare or societal costs, or both. Cost-effectiveness analyses should have reported incremental difference in cost and outcome between CR and control (e.g. cost per quality-adjusted life year (QALY) or cost per life year gained (LYG) analysis).

**Search methods for identification of studies**

**Electronic searches**

We updated the search from the previously published Cochrane Review (Anderson 2016), by searching the following databases on 1 September 2020.

- Cochrane Central Register of Controlled Trials (CENTRAL) in the Cochrane Library (Issue 9, 2020).
- Epub Ahead of Print, In-Process & Other Non-Indexed Citations, MEDLINE Daily and MEDLINE (Ovid; 1946 to 1 September 2020).
- Embase (Ovid; 1980 to 2020 week 36).
- Cumulative Index to Nursing and Allied Health Literature (CINAHL) Plus (EBSCOHost; 1937 to 1 September 2020).
- SCI-Expanded and CPCI-S on Web of Science (Clarivate Analytics; 1990 to 1 September 2020).

We designed search strategies with reference to those of the previous systematic review (Anderson 2016). We searched the databases using a strategy combining subject headings and free text terms relating to exercise-based rehabilitation and coronary heart disease, with filters applied to limit to RCTs. The RCT filter for MEDLINE is the Cochrane sensitivity-maximising RCT filter, and for Embase, terms as recommended in the Cochrane Handbook for Systematic Reviews of Interventions have been applied (Lefebvre 2019, hereafter referred to as the Cochrane Handbook). For the other databases, except CENTRAL, we applied an adaptation of the Cochrane RCT filter.

We applied date limits to the previously used search terms, and we searched for the new terms without date limits. We imposed no language or other limitations. We also gave consideration to variations in terms used and spellings of terms in different countries so that studies were not missed by the search strategy because of such variations. See Appendix 2 for details of the search strategies used.

**Searching other resources**

We searched the following clinical trial registers on 21 June 2021, for ongoing clinical trials.

- World Health Organization (WHO) International Clinical Trials Registry platform (ICTRP) (apps.who.int/trialsearch/).
- ClinicalTrials.gov (www.clinicaltrials.gov).

We also handsearched reference lists of retrieved articles and systematic reviews published since the last update, for any studies not identified by the electronic searches, and we sought expert advice.
Data collection and analysis

Selection of studies
Two review authors (JF, RST) independently examined the titles and abstracts of citations identified by the electronic searches for possible inclusion, and coded them as ‘retrieve’ (eligible or potentially eligible/unclear) or ‘irrelevant’. We retrieved full-text publications of potentially relevant studies (and had them translated into English where required), and two review authors (JF, GD) then independently determined study eligibility using a standardised inclusion form. We resolved any disagreements about study eligibility through discussion and, if necessary, a third review author (RST) was asked to arbitrate. We identified and excluded duplicates and collated multiple reports of the same study so that each study, rather than each report, is the unit of interest in the review. We recorded the selection process in sufficient detail to complete a PRISMA flow diagram and ‘Characteristics of excluded studies’ table (Liberati 2009).

We re-screened full texts excluded in previous versions of this review, where the reason for exclusion was based on reporting of outcomes. None of these studies were eligible for inclusion; we updated the reasons for exclusion.

Data extraction and management
Two review authors (GD, JF) independently extracted study characteristics of included RCTs and outcome data using a standardised data collection form which had been piloted on two RCTs included in the review. A third review author (RST) checked all extracted data for accuracy. We resolved disagreements by consensus. If data were presented numerically (in tables or text) and graphically (in figures), we used the numeric data because of possible measurement error when estimating from graphs. A third review author (RST) confirmed all numeric calculations and extractions from graphs or figures. We resolved any discrepancies by consensus. One author (GD) transferred extracted data into Review Manager 5.4.1 (Review Manager 2014), and a second author (RST) spot-checked data for accuracy against the included study. The following categories of data were extracted.

- Methods: study design, total duration of study, length of follow-up, number of centres, setting, date of study conduct.
- Participants: number randomised, number lost to follow-up, number analysed, age, sex, ethnicity, CHD diagnosis, and inclusion and exclusion criteria.
- Intervention and control: mode of exercise, duration, frequency and intensity, any co-interventions and description of comparator.
- Outcome: primary and secondary outcomes.
- Funding and notable conflicts of interest of authors.

If there were multiple reports of the same study, we assessed the duplicate publications for additional data. We extracted outcome results at all follow-up points post-randomisation. We contacted study authors where necessary to provide additional information.

Assessment of risk of bias in included studies
Two review authors (GD, JF) assessed the risk of bias in included studies using the Cochrane Collaboration’s risk of bias (RoB) tool, which is a domain-based critical evaluation of the following core risk of bias items: the quality of random sequence generation and allocation concealment, blinding of outcome assessment, incomplete outcome data, and selective reporting (Higgins 2011).

All risk of bias assessments were checked by a third review author (RST), and we resolved any discrepancies by consensus. Details of the assessments of risk of bias for each included trial are shown in the Characteristics of included studies tables.

Measures of treatment effect
We processed data in accordance with the Cochrane Handbook (Deeks 2011). Dichotomous outcomes for each comparison have been expressed as risk ratios (RR) with 95% confidence intervals (CI). For primary outcomes with an effect excluding no difference, we calculated the number needed to treat for an additional beneficial/harmful outcome (NNTB/NNTH), following methods detailed in the Cochrane Handbook (Schünemann 2021). We used the assumed risk with control from the ‘Summary of findings 1’ table as the ‘assumed comparator risk’.

Continuous HRQoL outcome comparisons were pooled where possible; that is, when there were more than two studies using the same HRQoL measure and reporting results on the same scale using the mean difference (MD). We interpreted these data using published minimal clinically important differences (MCIDs) where available. For the SF-36 instrument, within-person MCIDs which vary according to domain, have been published for people with heart disease (Wyrwich 2004; 15 for physical functioning, general health and mental health; 16.7 for emotional performance; 18.75 for physical performance and vitality; 20 for bodily pain; and 25 for social functioning). There are none available for the SF-36 summary component scores. For the EQ-5D, an MCID of 0.05 was used for interpretation (Briggs 2017).

Unit of analysis issues
Some trials contained two arms of CR and a single control group. In these cases, we divided the number randomised to the control group in half to obtain the denominator for data analysis; the means and standard deviation for the control group remained unchanged for both comparisons. For trials with cluster randomisation, approximately correct analyses were attempted where sufficient information (the intracluster correlation coefficient (ICC)) was available.

Given the variation in trial reporting follow-up timings, we pooled outcome results separately at three time points; namely, short-term (6 to 12 months); medium-term (> 12 to 36 months); and long-term (> 36 months) follow-up.

Dealing with missing data
We contacted multiple authors to verify key study characteristics (such as randomisation), data queries and obtain missing numerical outcome data.

Assessment of heterogeneity
We explored heterogeneity amongst included studies qualitatively (through visual inspection of forest plots and by comparing the characteristics of included studies), and quantitatively (using the Chi² test of heterogeneity and the I² statistic). We considered the magnitude and direction of effects, and strength of evidence for heterogeneity (e.g. P value from Chi² and number of studies).
alongside a threshold of $I^2$ greater than 50% to represent substantial heterogeneity (Deeks 2011).

Assessment of reporting biases

When 10 or more studies were included in meta-analysis, we used the funnel plot and Egger test to examine small study bias (Egger 1997). We processed data in accordance with the Cochrane Handbook (Deeks 2011). We completed data synthesis and analyses using Review Manager 5.4.1 software (Review Manager 2014) and STATA version 16.1 (StataCorp 2020).

Data synthesis

We performed random-effects meta-analyses with 95% CIs where appropriate (i.e. when treatments, participants, and the underlying clinical question were similar enough for pooling to make sense). We used random-effects meta-analyses due to the qualitative clinical heterogeneity (types of interventions and CHD population characteristics). Compared with a fixed-effect model, this model provides a more conservative statistical comparison of the difference between intervention and control by typically providing a wider confidence interval around the effect estimate. If a statistically significant difference was present using the random-effects model, we also reported the fixed-effect pooled estimate and 95% CI, because of the tendency of smaller trials - which are more susceptible to publication bias - to be over-weighted with a random-effects analysis (Hera 2008a; Hera 2008b).

Subgroup analysis and investigation of heterogeneity

We undertook univariate meta-regression to explore heterogeneity and examine potential treatment effect modifiers. We tested ten hypotheses that there may be differences in the effect of exercise-based CR on total mortality, cardiovascular mortality, total MI, revascularisation (CABG and PCI) and all-cause hospitalisation across the following pre-defined subgroups.

- CHD case mix (% participants presenting with MI).
- 'Dose' of exercise intervention (dose (units) = number of weeks of exercise training x average number of sessions/week x average duration of session in minutes).
- Type of CR (exercise-only CR versus comprehensive CR).
- Length of follow-up period (where trial reported multiple follow-up times, the longest follow-up was used).
- Year of publication (pre-1995 versus post-1995, where 1995 is used as proxy time to represent implementation of what might be regarded as 'modern CHD usual care').
- Overall sample size (N ≤ 150 versus N > 150).
- Setting (home- or centre-based CR).
- Risk of bias (low risk of bias in < 3 out of 5 domains).
- Study location (continent - Europe, North America, Australia/ Asia or Other)
- Studies undertaken in low-, middle- or high-income countries (according to the World Bank Group) (worldbank.org).

Given the relatively small ratio of trials to covariates, meta-regression was limited to univariate analysis (Deeks 2011). To account for multiple testing, a Bonferroni correction was used and a P value of less than 0.005 (0.05/10 covariates) was used to define statistical significance.

Sensitivity analysis

We did not undertake sensitivity analyses.

Summary of findings and assessment of the certainty of the evidence

One author (GD) used GRADEPro software to assess the certainty of evidence for primary outcomes reported in the review (GRADEpro GDT). We downgraded the evidence from high certainty by one level based on the following factors: indirectness of evidence, unexplained heterogeneity, publication bias, risk of bias due to study design limitations, and imprecision of results (Balshem 2011). A second author (RST) checked the assessment. We applied a GRADE assessment to the primary outcomes at 6 to 12 months (the most commonly reported follow-up timing across trials).

RESULTS

Description of studies

Details of the studies included in the review are listed in the Characteristics of included studies table. Details of excluded studies are listed in the Characteristics of excluded studies table.

Results of the search

In summary, a total of 85 trials reporting data for a total of 23,430 participants have been included in this review update. This includes 30 trials (55 publications, 9552 participants) from the original Cochrane Review (Jolliffe 2001) (Andersen 1981; Bell 1998; Bengtsson 1983; Bertie 1992; Bethell 1990; Carlsson 1998; Carson 1982; DeBusk 1994; Engblom 1996; Erdman 1986; Fletcher 1994; Fridlund 1991; Haskell 1994; Heller 1993; Holmback 1994; Kallio 1979; Leizorovicz 1991; Lewin 1992; Miller 1984; Oldridge 1991; Ornish 1990; Schuler 1992; Shaw 1981; Sivarajan 1982; Specchia 1996; Stern 1983; Vecchio 1981; Vermeulen 1983; WHO 1983; Wilhelmsen 1975); 17 studies (26 publications, 2211 participants) identified by the second updated search (Hera 2011) (Belardelli 2001; Bäck 2008; Dugmore 1999; Giallauria 2008; Hofman-Bang 1999; Kovo 2006; La Rovere 2002; Marchionni 2003; Seki 2003; Seki 2008; Stähle 1999; Toobert 2000; VHSG 2003; Yu 2003; Yu 2004; Zwischer 2008); an additional 16 trials (20 publications, 3872 participants) from the third updated search (Anderson 2016) (Arnon 2010; Bettencourt 2005a; Briffa 2005; Hambrecht 2004; Higgins 2001; Houle 2012; Maddison 2014; Maroto 2005; Munk 2009; Mutwali 2012; Oerkild 2012; Reid 2012; Roman 1983; Sandström 2005; Wang 2012; West 2012), as well as one publication (Dorn 1999) which provided further follow-up data from a study included in the original review (Shaw 1981); and 22 trials (43 publications, 7795 participants) from this 2020 updated search (Arnon 2019; Bubnova 2019; Bubnova 2020; Byrkjeland 2015; Campo 2020; Chavez 2019; Dorje 2019; Hassan 2016; Hautala 2017; He 2020; Lear 2015; Ma 2020; Pal 2013; Pomshekina 2017; Prabhakaran 2020; Santaurialia 2017; Snoek 2020; Sun 2016; Uddin 2020; Xu 2017; Zhang 2018). The study selection process is summarised in the PRISMA flow diagram shown in Figure 1 (Liberati 2009).

Included studies

Study design

Seventy-nine (93%) of the studies were two-arm parallel RCTs. Three studies compared more than two arms (Bubnova 2020; Pomeshkina 2017; Sivarajan 1982), and one study compared three arms with a waiting-list control design (Chaves 2019) (only outcome data at six months were used in this review as waiting-list control participants elected which arm of the study to move into after this point). One study used quasi-randomisation methods based on week of surgery (Uddin 2020). One study was a cluster-randomised trial (Heller 1993), with clustered data reported at the individual level, and no report of the ICC; therefore, we were unable to attempt to approximately correct the analyses. Given that the study sample size and number of events were small, the implications are expected to be minimal.

Setting

The majority of studies (48/85, 56%) were undertaken in Europe as single centre (61/85, 72%) studies. Most trials were relatively small in sample size (median 137, range: 25 to 3959). Three large trials contributed approximately 40% (8956 participants) of all included participants (Prabhakaran 2020; WHO 1983; West 2012). The median duration of trial intervention was 6 months (range 3 weeks to 42 months) with median overall trial follow-up of 12 months (range 6 to 228 months). Sixteen trials identified in this most recent update were undertaken in low- and middle-income countries (LMICs) (Aronov 2019; Bubnova 2019; Bubnova 2020; Chaves 2019; Dorje 2019; Hassan 2016; He 2020; Ma 2020; Pal 2013; Pomeshkina 2017; Pomeshkina 2019; Prabhakaran 2020; Sun 2016; Uddin 2020; Xu 2017; Zhang 2018), although the majority of trial evidence overall remained from high-income settings (64/85, 75%).

Participants

People with MI alone were recruited in 40 trials (47%, 17,085 participants), with one trial (He 2020) recruiting people with MI in the absence of obstructive coronary artery disease (MINOCA). The remaining trials recruited people suffering exclusively from angina (5 trials, 6%, 368 participants), post-CABG patients (7 trials, 8%, 983 participants), post-PCI patients (7 trials, 8%, 1035 participants) or a mixed population of people with CHD (26 trials, 31%, 3959). Two trials included a mixed indication population, where more than 50% had a CHD diagnosis: one included 4 people (2%) who received valve replacement surgery (Snoek 2020). The inclusion of these people is unlikely to have implications for the findings. Additionally, Zwissler 2006 included people with congestive heart failure (12%), and those at high risk of ischaemic heart disease (30%). However, the authors kindly provided separate outcome data for the ischaemic heart disease population only. The mean age of participants within the trials ranged from 47 to 77 years. Although over half of the trials included women (62 trials, 73%), and in the last decade the median percentage of female participants has increased from 11% to 18%, women accounted for fewer than 15% of the participants recruited overall.

Interventions

Thirty-eight of the 85 (45%) trials involved exercise-only interventions, and 47 (55%) trials involved interventions comprised of multiple components. Of the 47 trial interventions that included other elements, 20 (43%) were made up of exercise plus education components; 16 (34%) were made up of exercise, education and psychosocial components; 7 (15%) were made up of exercise plus psychosocial components; and four (9%) were made up of exercise plus other components such as controlled diets or dietary advice, risk factor management, smoking cessation and relaxation. One study randomised participants to receive exercise only, exercise plus education, or usual care (Chaves 2019). One study compared exercise only, or exercise plus education plus psychosocial components, to usual care control (Sivarajan 1982).

The mode of exercise training in CR programmes was most often aerobic in nature and most commonly static cycling, walking or circuit training. Twenty-two (26%) trials specifically reported the inclusion of resistance training, most commonly in the form of weight training, calisthenics or exercises using elastic bands. The ‘dose’ of exercise intervention (dose (units) = number of weeks of exercise training x average number of sessions/week x average duration of session in minutes) ranged considerably across trials: overall dose (median 3540, range 450 to 32,760 units); frequency (1 to 7 sessions/week); session length (20 to 90 minutes/session); and intensity (50% to 90% of maximal heart rate, peak heart rate or heart rate reserve; 50% to 95% of maximal oxygen uptake (VO₂ max); Borg rating of perceived exertion 11 to 16). Due to poor and inconsistent reporting of adherence and fidelity to exercise programmes in the RCTs, we were not able to consider the actual amount of exercise that the participants received or performed in this review.

Twenty-one studies (25%) were conducted in an exclusively home-based setting (Bäck 2008; Belardinelli 2001; Bell 1998; DeBusk 1994; Dorje 2019; Fletcher 1994; Haskell 1994; Heller 1993; Higgins 2001; Houle 2012; Lear 2015; Lewin 1992; Ma 2020; Maddison 2014; Miller 1984; Mutwalli 2012; Oerkild 2012; Reid 2012; Snoek 2020; Uddin 2020; Wang 2012), with four of these studies randomising participants to usual care, or to an electronically-delivered intervention designed with an element of personally
tailored or structured exercise, accessed via a mobile phone or the Internet (Dorje 2019; Lear 2015; Maddison 2014; Reid 2012).

Comparators

In general, comparator groups were described as receiving usual or standard care (50/85, 59%). Twenty-four trials (28%) reported participants in the control groups receiving usual care plus education, guidance or advice about diet, exercise, or physical activity from medical professionals or via information leaflets, but no formal exercise training. Eight trials (9%) reported participants in the control group simply received “no exercise”. One trial compared exercise training to stent angioplasty for participants with stable angina (Hambrecht 2004), while another compared exercise training to an “early return to normal activities group”, where participants returned to work two weeks following a myocardial infarction, without a formal CR programme (Kvoor 2006). A third trial provided participants in the control group with blinded pedometers and instructions about how to wear the pedometer correctly during seven consecutive days from morning to bedtime (Houle 2012).

Outcomes

Eighty studies (94%) measured and reported outcomes that were used in at least one quantitative analysis (meta-analysis or vote-counting for HRQoL and cost-effectiveness). One study reported clinical events as part of a composite outcome (Byrkjeland 2015). Two studies indicated that outcomes of interest were measured but did not report the results (Pomeshkina 2017; Pomeshkina 2019); trialists did not respond to our requests for data.

Funding

Fifty trials (59%) were funded by not-for-profit organisations, one trial (1%) was funded by industry, and six trials (7%) were funded by a combination of industry and not-for-profit organisations. Twenty-eight trials (33%) did not report funding sources.

Excluded studies

We excluded 201 publications identified in the current search, for reasons listed in the Characteristics of excluded studies table. The most common reasons for exclusion were associated with study design, which included insufficient follow-up time, or that the study was not a randomised controlled trial, or the comparator intervention included an exercise component.

We describe 15 ongoing trials which meet the inclusion criteria of this review in the Characteristics of ongoing studies table. Fourteen studies are awaiting classification, pending clarification from the authors regarding study characteristics (see Characteristics of studies awaiting classification).

Risk of bias in included studies

The overall risk of bias was low or unclear (Figure 2). A number of trials failed to give sufficient detail to assess their potential risk of bias, although the quality of reporting has generally improved over the last decade, with the percentage of studies with less than three low risk of bias domains decreased from 80% to 55% over the last decade.

Figure 2. (Continued)
Allocation

All the trial publications insufficiently detailed to assess whether the method was appropriate. A total of 30/85 (35%) studies reported details of appropriate generation of the random sequence (Andersen 1981; Bell 1998; Bethell 1990; Briffa 2005; Bubnova 2020; Byrkjeland 2015; Campo 2020; Chaves 2019; Dorje 2013; Erdman 1986; Hambrecht 2004; Haskell 1994; He 2020; Holmbach 1994; Houle 2012; Lear 2015; Ma 2020; Maddison 2014; Munk 2009; Oerkild 2012; Pal 2013; Pomeshkina 2017; Prabhakaran 2020; Reid 2012; Santaularia 2017; Snoek 2020; Sun 2016; Wang 2012; Wilhelmsen 1975; Zwisler 2008), and 23/85 (27%) studies reported appropriate concealment of allocation (Bell 1998; Briffa 2005; Bubnova 2020; Byrkjeland 2015; Campo 2020; Chaves 2019; Dorje 2013; Haskell 1994; Holmbach 1994; Kovoor 2006; Lear 2015; Ma 2020; Maddison 2014; Munk 2009; Oerkild 2012; Pal 2013; Prabhakaran 2020; Reid 2012; Schuler 1992; Snoek 2020; VHSG 2003; West 2012; Zwisler 2008). One study used quasi-randomisation methods (Uddin 2020), allocating participants to CR or usual care according to the week of surgery for participants.

Blinding

Given the nature of the exercise-based CR intervention, it is not possible to blind participants or programme personnel.

Incomplete outcome data

Although losses to follow-up and dropout were relatively high in some studies (up to 48% in trials where losses to follow-up were reported), follow-up of 80% or more was achieved in 59/85 (69%) studies (Andersen 1981; Aronov 2010; Aronov 2015; Bäck 2001; Belardinelli 2001; Bell 1998; Bethell 1990; Bettencourt 2000a; Briffa 2005; Campo 2020; Carlsson 1998; Dorje 2019; Dugmore 1999; Engblom 1996; Giallauria 2008; Hambrecht 2004; Haskell 1994; Hassan 2016; He 2020; Heller 1993; Holmback 1994; Kallio 1979; La Rovere 2002; Lear 2015; Leizorovicz 1991; Lewin 1992; Ma 2020; Maddison 2014; Mandhata 2000; Marchioni 2003; Maroto 2005; Miller 1984; Munk 2009; Oerkild 2012; Oldridge 1991; Pomeshkina 2017; Pomeshkina 2019; Prabhakaran 2020; Roman 1983; Sandstrom 2005; Schuler 1992; Seki 2003; Shaw 1981; Snoek 2020; Specchia 1996; Stähle 1999; Stern 1983; Toobert 2000; Vermeulen 1983; VHSG 2003; Wang 2012; West 2012; Wilhelmsen 1975; Yu 2003; Zhang 2018; Zwisler 2008). However, reasons for loss to follow-up and dropout were often not reported. We judged only 38/85 (44%) studies to have adequately reported reasons for loss to follow-up and whether there were systematic differences between groups with respect to missing data, thus having a low risk of bias. We judged 40/85 (47%) studies as having a high risk of bias, and seven studies as having an unclear risk of bias.

Selective reporting

The majority (62/85; 73%) of trials reported all outcomes listed in their methods sections, or that were prespecified in the study protocol or trial registration (Campo 2020; Chaves 2019; Dorje 2019; Fridlund 1991; Prabhakaran 2020; Santaularia 2017; Snoek 2020). Nine trials failed to report all outcomes at all time points collected (Dorje 2019; La Rovere 2002; Manchanda 2000; Oerkild 2012; Ornish 1990; Pomeshkina 2017; Pomeshkina 2019; Specchia 1996; Toobert 2000), and we judged 11 studies as having an unclear risk of bias as their methods sections did not clearly describe the outcomes to be collected (Aronov 2019; Bubnova 2019; Bubnova 2020; Byrkjeland 2015; Hassan 2016; Hautala 2017; He 2020; Ma 2020; Pal 2013; Sun 2016; Uddin 2020; Wilhelmsen 1975; Xu 2017; Zhang 2018). A number of the included studies were not designed to assess treatment group differences in morbidity and mortality (as these were not the primary outcomes of these trials) and, therefore, may...
not have fully reported all clinical events that occurred during the follow-up period.

**Other potential sources of bias**

We did not find any other potential sources of bias amongst the studies.

**Effects of interventions**

See: **Summary of findings 1** Exercise-based cardiac rehabilitation compared to 'no exercise' control for coronary heart disease

Where data were available, we have presented pooled outcomes at three follow-up timings: short-term (6 to 12 months); medium-term (> 12 to 36 months); and long-term (> 36 months).

**Primary outcomes**

**All-cause mortality**

Sixty-one of the 85 included studies (72%) reported all-cause mortality ([Analysis 1.1](#)). Four trials contributed mortality data at more than one follow-up period ([Shaw 1981; West 2012; WHO 1983; Wilhelmsen 1975](#)). Fourteen trials reported zero events in both the intervention and control groups up to 12 months' follow-up ([Aronov 2019; Byrkjeland 2015; Chaves 2019; Hambrecht 2004; Houle 2012; Kovoor 2006; Maddison 2014; Manchanda 2000; Munk 2009; Pomeshkina 2017; Ponoshkina 2019; Santaularia 2017; Seki 2008; Zhang 2018](#)).

Compared with 'no exercise' control, exercise-based CR likely results in a slight reduction in all-cause mortality up to 12 months' follow-up (RR 0.87, 95% CI 0.73 to 1.04; I² = 0%; 25 trials, 26 comparisons, 8823 participants). The certainty of the evidence was moderate due to imprecision, with a wide confidence interval. There was no evidence of publication bias for all-cause mortality up to 12 months' follow-up ([Figure 3](#); Egger test: P = 0.50).

At medium- and long-term follow-up, exercise-based CR may result in little to no difference in all-cause mortality (medium-term: RR 0.90, 95% CI 0.80 to 1.02; I² = 0%; 16 trials, 11,073 participants; long-term: RR 0.91, 95% CI 0.75 to 1.10; I² = 35%; 11 trials, 3828 participants). There was no evidence of publication bias for all-cause mortality at medium- or long-term follow-up ([Figure 4](#); Egger test: P = 0.54; [Figure 5](#); Egger test: P = 0.15, respectively).
Figure 4. Funnel plot of comparison: exercise-based rehabilitation versus usual care, outcome 1.1: all-cause mortality at > 36 months' follow-up
Cardiovascular mortality

Thirty-three of the 85 trials (39%) reported cardiovascular mortality (Analysis 1.2). One trial reported both short- and medium-term follow-up (WHO 1983). Up to 12 months’ follow-up, five trials reported zero events in both the intervention and control group (Byrkjeland 2015; Chaves 2019; Maddison 2014; Munk 2009; Seki 2008). At medium-term follow-up, one trial reported zero events in both the intervention and control groups (Belardinelli 2001).

Exercise-based CR likely results in little to no difference in cardiovascular mortality up to 12 months’ follow-up (RR 0.88, 95% CI 0.68 to 1.14; I² = 0%; 15 trials, 5360 participants). This result may be driven by the WHO 1983 trial which carries the majority of the weight. The certainty of the evidence was moderate due to imprecision, with a wide confidence interval. There was no evidence of publication bias for cardiovascular mortality (Figure 6; Egger test: P = 0.76).
However, at medium-term follow-up, evidence suggests exercise-based CR results in a large reduction in cardiovascular mortality (RR 0.77, 95% CI 0.63 to 0.93; I² = 5%; 5 trials, 3614 participants), but again, this result may be driven by the WHO 1983 trial which accounts for the majority of the weight. Similarly, at long-term follow-up, evidence suggests a large reduction in cardiovascular mortality (RR 0.58, 95% CI 0.43 to 0.78; I² = 0%; 8 trials, 1392 participants).

**Fatal or non-fatal myocardial infarction**

Forty-two of the 85 trials (49%) reported the risk of fatal or non-fatal MI (Analysis 1.3). Three trials reported zero events in both the intervention and control groups up to 12 months’ follow-up (Maddison 2014; Reid 2012; Seki 2008). Five studies contributed MI data at multiple follow-up time points (Hambrecht 2004; Haskell 1994; Hofman-Bang 1999; West 2012; WHO 1983).

Exercise-based CR likely results in a large reduction in fatal or non-fatal MI up to 12 months’ follow-up (RR 0.72, 95% CI 0.55 to 0.93; I² = 7%; 22 trials, 24 comparisons, 7423 participants). The NNTB is 75 (95% CI 47 to 298), meaning one additional MI could be prevented up to 12 months for every 75 people participating in exercise-based CR. The certainty of the evidence was high, and there was no evidence of publication bias (Figure 7; Egger test: P = 0.12).
Figure 7. Funnel plot of comparison: exercise-based rehabilitation versus usual care, outcome 1.3: myocardial infarction at 6 to 12 months’ follow-up

The evidence suggests there may be little to no difference for risk of MI with exercise-based CR at medium-term follow-up (RR 1.07, 95% CI 0.91 to 1.27, I² = 0%; 12 trials, 9565 participants), which may be driven by the WHO 1983 study which carries more weight than other studies included in this analysis. There was no evidence of publication bias at medium-term follow-up (Figure 8; Egger test: P = 0.18).
At long-term follow-up, the evidence suggests that exercise-based CR results in a large reduction in risk of fatal or non-fatal MI (RR 0.67, 95% CI 0.50 to 0.90; $I^2 = 0\%$; 10 trials, 1560 participants). There was no evidence of publication bias at long-term follow-up (Figure 9; Egger test: $P = 0.19$).
Figure 9. Funnel plot of comparison: exercise-based rehabilitation versus usual care, outcome 1.1: myocardial infarction at > 36 months' follow-up

**Revascularisation - CABG**

Thirty-one of the 85 included trials (36%) reported the risk of CABG (Analysis 1.4). Four studies contributed CABG data at multiple follow-up time points (Haskell 1994; Hofman-Bang 1999; Stahle 1999; West 2012). Two studies reported zero events in both the intervention and control groups up to 12 months' follow-up (Maddison 2014; Seki 2008).

There was little to no difference between exercise-based CR and 'no exercise' control for CABG up to 12 months' follow-up (RR 0.99, 95% CI 0.78 to 1.27; $I^2 = 0\%$; 20 trials, 22 comparisons, 4473 participants). The certainty of evidence was high, and there was no evidence of publication bias for CABG at short-term follow-up (Figure 10; Egger test: $P = 0.10$).
Similarly, at medium-term follow-up, evidence suggests little to no difference between exercise-based CR and ‘no exercise’ control in risk of CABG (RR 0.97, 95% CI 0.77 to 1.23; I² = 0%; 9 trials, 2826 participants), whereas across the small number of studies reporting CABG at long-term follow-up, evidence was uncertain about the effect of exercise-based CR on risk of CABG, with a wide 95% CI including considerable benefit and harm (RR 0.66, 95% CI 0.34 to 1.27; I² = 18%; 4 trials, 675 participants).

Revascularisation - PCI

Twenty-one of the 85 included trials (25%) reported the risk of PCI (Analysis 1.5). Four studies contributed PCI data at multiple follow-up time points (Haskell 1994; Hofman-Bang 1999; Stahle 1999; West 2012). Three studies reported zero events in both the intervention and control groups up to 12 months’ follow-up (Maddison 2014; Reid 2012; Seki 2008).

Exercise-based CR likely results in little to no difference in PCI up to 12 months’ follow-up (RR 0.86, 95% CI 0.63 to 1.19; I² = 7%; 13 trials, 14 comparisons, 3465 participants). The certainty of evidence was moderate due to imprecision, with wide confidence intervals. There was no evidence of publication bias for PCI at short-term follow-up (Figure 11; Egger test: P = 0.94).
At medium-term and long-term follow-up, the evidence is uncertain whether there is a benefit for risk of PCI with exercise-based CR as the 95% CI is consistent with possible benefit and possible harm (medium-term: RR 0.96, 95% CI 0.69 to 1.35; $I^2 = 26$%; 6 trials, 1983 participants; long-term: RR 0.76, 95% CI 0.48 to 1.20; $I^2 = 0$%; 3 trials, 567 participants).

**All-cause hospitalisation**

Twenty-three of the 85 included studies (27%) reported all-cause hospital admissions (Analysis 1.6). One study reported follow-up at both short- and medium-term (Hofman-Bang 1999). One trial reported zero events in both the intervention and control groups at up to 12 months' follow-up (Maddison 2014). No trials reported hospitalisation data at long-term follow-up.

Exercise-based CR probably results in a large reduction in all-cause hospital admissions up to 12 months' follow-up (RR 0.58, 95% CI 0.43 to 0.77; $I^2 = 42$%; 14 trials, 16 comparisons, 2030 participants). The NNTB is 12 (95% CI 9 to 21) meaning one additional hospital admission for any cause could be prevented up to 12 months for every 12 people participating in exercise-based CR. The certainty of evidence was moderate, downgraded because of evidence of publication bias (Figure 12; Egger test: $P = 0.003$).
At medium-term follow-up, evidence suggests exercise-based CR may result in little to no difference in all-cause hospitalisation (RR 0.92, 95% CI 0.82 to 1.03; I² = 0%; 9 trials, 5995 participants).

**Cardiovascular hospitalisation**

Eight studies reported cardiovascular hospital admissions (Analysis 1.7). One study contributed cardiovascular hospital admission data over two follow-up time points (Haskell 1994). No trials reported data at long-term follow-up. Definitions of cardiovascular hospitalisation differed somewhat between trials (Campo 2020: hospitalisations for a cardiovascular cause (acute coronary syndrome (ACS), cerebrovascular accident, heart failure, chronic coronary syndrome; Hambrecht 2004: hospitalisation and coronary angiography owing to worsening angina; Haskell 1994: cardiac events initiating hospitalisation (death, MI, CABG, percutaneous transluminal coronary angioplasty (PTCA)); Mutwalli 2012: elevated heart rate, deep sternal infection and heart attack; Reid 2012: rehospitalised with chest pain; Snoek 2020: hospitalisation for cardiac reasons (chronic coronary syndrome, ACS, pacemaker, PCI, endocarditis, dyspnoea); VHSG 2003: chest pain without objective evidence of ischaemia; Zwisler 2008: acute first-time readmissions due to heart disease).

We are uncertain whether exercise-based CR may result in reduced risk of cardiovascular hospital admissions up to 12 months' follow-up (RR 0.80, 95% CI 0.41 to 1.59; I² = 53%; 6 trials, 1087 participants). The certainty of evidence was low due to evidence of substantial heterogeneity and a wide confidence interval including considerable benefit as well as harm.

Similarly, evidence is uncertain in risk of cardiovascular hospitalisation in the few studies that reported medium-term follow-up (RR 0.92, 95% CI 0.76 to 1.12; I² = 0%; 3 trials, 943 participants). There were insufficient studies to assess publication bias.

**Secondary outcomes**

**Health-related quality of life**

Fifteen trials (18%) measured HRQoL at short-term follow-up using the same validated measure and reported outcomes on the same scale, enabling meta-analyses using MD to be performed. For each of these validated measures, an increase in score indicates improvement in HRQoL. There were not enough data reported across trials at medium- and long-term follow-up for meta-analysis to be performed.

Six studies (1731 participants) reported the SF-36 summary scores (physical component score (PCS) and mental component score (MCS) at short-term follow-up (Analysis 1.8). Exercise-based CR may slightly increase PCS compared to ‘no exercise’ control (MD 1.70,
Eight studies (2812 participants) reported SF-36 individual domain scores (physical functioning, physical performance, bodily pain, general health, vitality, social functioning, emotional performance, mental health) at short-term follow-up (Analysis 1.0). One study did not report scores for the vitality and emotional performance domains (Belardinelli 2001). Exercise-based CR may result in an increase in six out of eight domains: physical functioning score (MD 8.47, 95% CI 3.69 to 13.24); physical performance (MD 8.08, 95% CI 2.89 to 13.27); general health (MD 5.66, 95% CI 2.08 to 9.25); vitality (MD 5.78, 95% CI 1.89 to 9.67); social functioning (MD 1.98, 95% CI 0.26 to 3.70; \( \text{I}^2 = 20\% \)); and mental health (MD 5.60, 95% CI 1.21 to 9.98). There was no difference in the domains bodily pain (MD -0.06, 95% CI -0.97 to 8.84) and emotional performance (MD 0.69, 95% CI -1.33 to 2.71; \( \text{I}^2 = 18\% \)). There was evidence of substantial heterogeneity for the following domains: physical functioning (\( \text{I}^2 = 92\% \), \( P < 0.001 \)); physical performance (\( \text{I}^2 = 87\% \), \( P < 0.001 \)); bodily pain (\( \text{I}^2 = 97\% \), \( P < 0.001 \)); general health (\( \text{I}^2 = 84\% \), \( P < 0.001 \)); vitality (\( \text{I}^2 = 85\% \), \( P < 0.001 \)); and mental health (\( \text{I}^2 = 93\% \), \( P < 0.001 \)). Based on the minimally important clinical differences reported by Wywich 2004, the increases in each of the domains are not clinically important.

Three studies (476 participants) reported EQ-5D visual analogue scores at short-term follow-up (Analysis 1.10). Exercise-based CR may increase EQ-5D scores up to 12 months' follow-up (MD 0.05, 95% CI -0.01 to 0.10; \( P = 0.08 \)). There was evidence of substantial heterogeneity (\( \text{I}^2 = 69\% \), \( P = 0.04 \)). The increase in EQ-5D could potentially be clinically meaningful (Briggs 2017).

In addition to the meta-analyses, given both the heterogeneity in HRQoL outcome measures and methods of reporting HRQoL (Table 1; Campbell 2020). Thirty-two of the 85 trials (38%; \( N = 7680 \) participants) assessed HRQoL using a range of validated generic (e.g. SF-36) or disease-specific (e.g. HeartQoL) outcome measures. Thirty of these trials reported HRQoL data at short-term follow-up, three reported HRQoL data at medium-term follow-up, and only one trial reported HRQoL data at long-term follow-up. Although most trials demonstrated an improvement in HRQL at follow-up compared to baseline following exercise-based CR, a within-group improvement was also often reported in control participants. Twenty trials reported higher levels of HRQoL in one or more subgroups with exercise-based CR compared to control at short-term follow-up (Belardinelli 2001; Bettencourt 2005a; Briffa 2005; Bubnova 2019; Bubnova 2020; Campo 2020; Hassan 2016; Hautala 2017; He 2020; Heller 1993; Hofman-Bang 1999; Houle 2012; Ma 2020; Maddison 2014; Mutwalli 2012; Reid 2012; Santaularia 2017; Uddin 2020; Wang 2012; Yu 2003), with three at medium-term follow-up (Bell 1998; Toobert 2000; Yu 2003), and one at long-term follow-up (Engblom 1996). In twelve trials, there was evidence of a significantly higher level of quality of life in most (> 50%) of the subgroups at short-term follow-up only (Belardinelli 2001; Bell 1998; Bubnova 2019; Bubnova 2020; Campo 2020; Hassan 2016; Hautala 2017; Ma 2020; Mutwalli 2012; Reid 2012; Uddin 2020; Wang 2012).

**Discussion**

**Summary of main results**

Exercise-based CR provides important benefits up to 12 months' follow-up, including a large reduction in fatal or non-fatal MI, and likely reductions in all-cause mortality and all-cause hospital admissions. There was evidence that exercise-based CR results in little to no difference in CABI, and likely results in little to no difference in cardiovascular mortality and PCI. Evidence was uncertain whether exercise-based CR may result in reduced risk of cardiovascular hospital admissions. Imprecision (wide 95% CI), publication bias and statistical heterogeneity led to downgrading the certainty of these outcomes up to 12 months' follow-up. At medium-term follow-up (> 12 to 36 months), although there may be little to no difference in all-cause mortality, MI, PCI, CABI and all-cause hospitalisation with exercise-based CR, a large reduction in cardiovascular mortality was found. The evidence was uncertain for difference in risk of cardiovascular hospitalisation.
At long-term follow-up (>3 years), evidence suggests that exercise-based CR may result in little to no difference in all-cause mortality, but may result in a large reduction in risks of cardiovascular mortality and MI. The evidence was uncertain for difference in risk of CABG and PCI.

Univariate meta-regression analysis showed that the impact of exercise-based CR on clinical events appears to be largely consistent across trials, irrespective of case mix (% of post-MI participants), type of rehabilitation (exercise-only versus comprehensive), dose of exercise training (number of weeks of exercise training × average number of sessions/week × average minutes/session), duration of follow-up (months), study location (continent - Europe, North America, Australia/Asia or other, or LMIC versus HIC setting), year of publication (pre-1995 versus post-1995), risk of bias (low risk in ≤3 items versus >3 items) or sample size (≤150 vs >150).

We did not undertake meta-analysis for all HRQoL outcomes, due to the range of outcome measures and methods of reporting. However, where meta-analysis was possible, there was evidence of some small increases in HRQoL with exercise-based CR compared with 'no exercise' control, across several SF-36 subscales (mental component, physical functioning, physical performance, general health, vitality, social functioning and mental health scores). However, these may not be clinically important differences. These findings were supported by a vote-counting approach to summarise HRQoL results across all studies reporting HRQoL, in which 23/32 (72%) trials reported higher levels of HRQoL in one or more subscales with exercise-based CR compared to control at follow-up. Whilst this method of synthesis without meta-analysis has significant limitations, such as not taking account of the differential weights given to each trial, we believe it to be the best available method to concisely and transparently summarise the results (Campbell 2020).

The five trial-based economic evaluation studies showed exercise-based CR to be a potentially cost-effective use of resources in terms of gain in QALYs.

Overall completeness and applicability of evidence

The generalisability of early versions of this review was limited, as most included studies recruited predominantly male participants (Jolliffe 2001: 9% female; current version: 16% female), following MI (Jolliffe 2001: 80% trials with MI only participants; current version: 47% trials with MI only participants). However, with the inclusion of more women in trials conducted in the last decade and with further data on the outcomes of hospitalisation and HRQoL, the findings of this updated review potentially have greater external validity. An additional 16 new studies identified and included in this current update have been undertaken in low- and middle-income countries, increasing the generalisability of our results to these countries where prevalence of CHD is high and continues to increase (Prabhakaran 2018).

Quality of the evidence

In previous versions of this review, the general lack of adequate reporting of randomisation and blinding methods in the included RCT reports made it difficult to assess their methodological quality. However, the quality of reporting in studies has increased over the last decade, and reassuringly, meta-regression showed no significant association between the effect of CR compared to control and the level of risk of bias across trials.

GRADE demonstrated that the certainty of the evidence ranged from low to high across the primary outcomes. We downgraded the certainty of the evidence for all-cause mortality, cardiovascular mortality, PCI and cardiovascular hospitalisations by one level for imprecision, due to wide confidence intervals that overlapped the boundary for no effect (i.e. 95% CI crossed 1). We downgraded the certainty of the evidence for MI and all-cause hospitalisations by one level due to evidence of publication bias (Egger test: P < 0.05). We downgraded the certainty of the evidence for cardiovascular hospitalisations by one level due to evidence of substantial heterogeneity (Chi² test: P < 0.05, or I² test for heterogeneity > 50%, or both).

Potential biases in the review process

We believe this is the most comprehensive systematic review to date of RCT-based evidence for the impact of exercise-based CR for people with CHD. However, it is important that we contextualise our review findings in light of some limitations.

Details of random allocation sequence generation and concealment, and blinding of outcome assessment were poorly reported (33% trials adequately reported allocation sequence generation and 29% trials adequately reported blinding of outcome assessment), and therefore may be subject to bias. Funnel plot asymmetry for the risk of MI and all-cause hospital admission is indicative of small-study bias and possible publication bias. There was also evidence of statistical heterogeneity for all-cause and cardiovascular hospitalisations, and all HRQoL subscales, except SF-12 MCS.

The number of trials reporting medium-term (>12 to 36 month follow-up) and long-term data (>36 months’ follow-up) has decreased from 47% (27/57 trials) to 21% (7/33 trials) over the last decade, while sample sizes have remained relatively small over the same period (median sample size increased from 125 to 142). As a result, the number of deaths and other clinical events, including hospitalisations, reported by many trials is small, or in some cases, zero. Indeed, in many studies, we located event data in the participant flow diagrams and descriptions of losses to follow-up and exclusions, rather than as prespecified outcomes measured, reported, or analysed within trials. In addition, cause of death was often not reported. Furthermore, in recent studies, clinical events have often been reported as a composite endpoint (e.g. major adverse cardiac events) rather than as individual events. These data reporting and evidence synthesis issues may have resulted in some of the apparently paradoxical findings of this review, such as reduced all-cause mortality but not cardiovascular mortality in the short term.

All included studies involved a ‘no formal exercise training’ intervention comparator. However, a wide range of comparators were seen across the trials, including education, psychological intervention or usual medical care alone. Due to poor and inconsistent reporting of adherence and fidelity to exercise programmes in the RCTs, we were not able to consider the actual amount of exercise that participants received or performed in this review.
Agreements and disagreements with other studies or reviews

The findings of this updated review are largely in accord with the previous version of this review. Although there was a trend towards a slight reduction in all-cause mortality with exercise-based CR compared to ‘no exercise’ control, this reduction failed to reach statistical significance. This is likely explained by the inclusion of more recent trials conducted in the era of optimal medical therapy. Given the proven survival advantage of contemporary medical treatments, and the limited opportunity for mortality gain in this patient cohort, any incremental mortality benefit with exercise is likely to be small. This theory is supported by Powell and colleagues’ meta-analysis of contemporary trials (Powell 2018), demonstrating no improvement in all-cause mortality across 19 trials (risk difference (RD) 0.00, 95% CI -0.02 to 0.01; P = 0.38), or 9 trials reporting cardiovascular mortality (RD -0.01, 95% CI -0.02 to 0.01; P = 0.25), published between 2000 and 2017. Our meta-regression analysis showed a potential trend (RR 0.84, 95% CI 0.70 to 0.99; P = 0.04) suggesting all-cause mortality could be somewhat associated with publication year. However, due to multiple testing, we cannot rule out that this finding was by chance, and did not meet the criteria for statistical significance once the Bonferroni correction was applied.

Our results are also somewhat consistent with the findings of a recently published comprehensive network meta-analysis (Huang 2021). In this study, the authors found that comprehensive exercise-based CR reduces the risk of all-cause mortality, yet unlike our results, risks of PCI and CABG revascularisation were also reduced. Exercise-only CR was found to reduce the risks of non-fatal MI, cardiovascular mortality, and all-cause and cardiovascular hospitalisation, but not the risk of all-cause mortality or revascularisations compared to standard care. The authors also similarly found no strong evidence to differentiate the relative benefits of exercise-based CR, whether delivered as an exercise-only intervention or a comprehensive intervention.

McGregor and colleagues performed a meta-analysis of exercise-based CR based on HRQoL outcomes of people with CHD, including 15 short-term (i.e. 1 to 6 months) and 9 medium-term (i.e. 8 to 12 months) trials (McGregor 2020). Pooled HRQoL results were consistent with the present review, showing improvement with CR across a number HRQoL domain scores.

The recently updated meta-analysis of the Cardiac Rehabilitation Outcome Study (CROSII), which included RCTs and prospective and retrospective cohort studies, reported a mortality benefit of CR in people with acute coronary syndrome or revascularisation, with an index event in 1995 or later (Salzwedel 2020). However, with inclusion of observational evidence, the prognostic benefit reported by the CROSII study is subject to selection bias and confounding.

Authors’ Conclusions

Implications for practice

This review shows that exercise-based cardiac rehabilitation (CR) provides important benefits by likely reducing risks of all-cause mortality, myocardial infarction (MI), all-cause hospitalisation and associated healthcare costs, and improving health-related quality of life (HRQoL) in people with coronary heart disease (CHD). There was an increase in the proportion of female participants in more recent trials. However, the application of this evidence base to more poorly-represented groups, particularly people with angina pectoris and higher-risk CHD, and those with major comorbidities, remains a question of clinical judgement. There appears to be little to choose between exercise-only CR or exercise in combination with psychosocial or educational CR interventions. In the absence of definitive cost-effectiveness conclusions comparing psychosocial or educational approaches to exercise-based CR, it would be rational to use cost considerations to determine practice. Finally, this update included a further 16 randomised controlled trials (RCTs) undertaken in low- and middle-income countries (LMICs), increasing the generalisability of our findings to these settings.

Implications for research

In spite of incorporation of recent trial evidence including more women, the population of people with CHD studied in this review remains predominately low-risk, middle-aged males following MI or revascularisation. Therefore, well-designed, and adequately-reported RCTs of CR in groups of people with CHD more representative of usual clinical practice are still needed. These trials need to explicitly report clinical events, including mortality and hospital admission; should include validated HRQoL outcome measures, especially over longer-term follow-up; and should assess costs and cost-effectiveness. Further details of the presentation and diagnoses of people with CHD, and interventions offered and received, should be reported in trials, so that results of future reviews can better stratify outcomes according to the range of CHD populations or types of CR interventions.

* Indicates the major publication for the study
Exclusion criteria: participants without motivation and participants with impairment of the motorial apparatus that excluded training

N randomised: total: 75; intervention: 38; comparator: 37

Diagnosis (% of participants): post MI: 100%

Age (mean ±SD): intervention: 52.2 ± 7.5; comparator: 55.6 ± 6.3

Percentage male: intervention: 100%; comparator: 100%

Ethnicity: NR

Interventions

Intervention: aerobic activity e.g. running, cycling, skipping + weights for 1 hour x 2 weekly for 2 months, then x 1 week for 10 months. Then continue at home.

Components: exercise only

Setting: centre-based initially, followed by home

Exercise programme modality: e.g. running, cycling, skipping

Length of session: 1 hour

Frequency: twice a week for two months, and then weekly for 10 months

Intensity: initial load of 150 kpm/min (24.5 W). increased with 150 kpm/min every 6 mins

Resistance training included? yes - weights

Total duration: 12 months

Co-interventions: none described

Comparator: non-trained group (although some participants trained on own initiative)

Co-interventions: none described

Outcomes

Total and CHD mortality

Non-fatal MI

Outcomes measured at 1, 13, 25 and 37 months post-discharge

Source of funding

NR

Conflicts of interest

NR

Notes

88 participants were randomised, but 13 failed to follow up. Therefore, 75 took part in the study.

Several participants in control group trained on own initiative, but were analysed as intention-to-treat. Trialists concluded that physical training after MI appears to reduce consequences and to improve PWC, but PWC declines once participant is on their own. Physical training had no effect on period of convalescence or return to work, but age and previous occupation were of significance.

### Study characteristics

**Methods**

- Study design: multicentre RCT (20 cities)
- Country: Russia
- Dates participants recruited: NR
- Maximum follow-up: 1 year

**Participants**

- Inclusion criteria: people 3 to 8 weeks after MI, unstable angina or reconstructive coronary arteries intervention. In some cases (at discretion of the researchers), people with stable angina after hospital treatment with unconfirmed diagnosis of MI or unstable angina were included in the study.
- Exclusion criteria: none reported
- N Randomised: total: 392; intervention: 197; comparator: 195
- Diagnosis (% of participants):
  - Stable angina: intervention: 62.7; comparator: 77.7
  - Post MI: intervention: 78.4; comparator: 77.3
  - Unstable angina: intervention: 5.0; comparator: 10.9
  - (not mutually exclusive)
- Age (mean ± SD): intervention: 51.9 ± 7.2; comparator: 51.9 ± 7
- Percentage male: intervention: 95.5; comparator: 91.7
- Ethnicity: NR

**Interventions**

- Intervention: participants of the main group received moderate-intensity PT (50% to 60% of the performed capacity by bicycle ergometry (BE) test) 3 times per week with duration of exercises from 45 minutes to 1 hour for 1 year
- Components: exercise only
- Setting: NR
- Exercise programme modality: cycling
- Length of session: 45-60 mins
- Frequency: 3 times a week
- Intensity: 50% to 60% of the performed capacity by bicycle ergometry test
- Resistance training included: No
Total duration: 1 year

Co-interventions: participants received standard medical therapy described below.

Comparator: participants received standard medical therapy which included beta-blocker, acetylsalicylic acid or other antithrombotic drug, as well as nitrate, and ACE inhibitor. Some participants took lipid-lowering drugs.

Co-interventions: none described

### Aronov 2019

#### Study characteristics

**Study design:** single-centre RCT

**Country:** Russia

**Dates participants recruited:** NR

**Maximum follow-up:** 12 months

**Inclusion criteria:** male participants with coronary artery disease that underwent CABG 3 to 8 weeks before enrolment

**Exclusion criteria:** early post-surgery stenocardia, pericarditis (diagnosed by echocardiography), pericardial effusion with a volume of pericardial fluid exceeding 200 mL, separation of the pericardial layers in diastole more than 1 cm, or moderate pericardial effusion with signs of inflammation), sternal diastasis and other post-surgery complications (impaired wound healing, suture sinuses or pain), car-
Cochrane Data b ase of S ystema tic R eview s

diac arrhythmia, heart failure, maximal power output in cycle ergometer test < 50 W, hypertension (≥ 180/100 mmHg), history of stroke or transient ischaemia, carotid artery narrowing by ≥ 50%, intermittent claudication syndrome, relapsing thromboembolism complications, severe diabetes mellitus, morbid obesity, pulmonary disorders, concurrent diseases that impede physical training.

**N randomised:** total: 36; intervention: 18; comparator: 18

**Diagnosis (% of participants):** intervention: received CABG 17 (94%), history of MI 13 (72.2%), history of angina 13 (72.2%); comparator: received CABG 17 (94%), history of MI 10 (55.6%), history of angina 15 (83.3%).

**Age (mean ±SD):** intervention: 58.6 ± 7.0; comparator 55.9 ± 7.0

**Percentage male:** 100%

**Ethnicity:** NR

| Interventions | Intervention: “School for coronary bypass patients” - an integrated cardiac rehabilitation program. Weekly group information sessions (60 to 80 min) under guidance by a cardiologist. Sessions focused on most common topics related to rehabilitation after CABG: cardiac diseases, cardiovascular risk factors, smoking cessation, stress management, anxiety and depression, and “hearthealthy” diet and cooking. Supervised physical training 3 times per week for 4 months. 60-minute sessions including breathing exercise, physical drill complexes and cycling on a stationary bicycle at moderate intensity (50% to 60% max. power assessed by graded cycle ergometer test). After 4 months centre-based CR, participants continued home-based exercise for 6 months. Participants provided with written instructions and a video with recommendations to follow the programme for a year. Participants instructed to perform self-assessment of their physical well being at home. Exercises included breathing, physical drill and walking.  
**Components:** exercise plus education plus individual counselling sessions upon request

**Setting:** centre- and then home-based

**Exercise programme modality:** breathing exercises, physical drills, centre-based stationary cycling, and home-based walking

**Length of session:** 1 hour

**Frequency:** three sessions per week

**Intensity:** 50% to 60% maximal power

**Resistance training included?** No

**Total duration:** 10 months

**Co-interventions:** none described

**Comparator:** control group participants attended the same educational sessions as intervention group. Participants received a recommendation to follow physical training at home on their own.

**Co-interventions:** none described

| Outcomes | Total mortality, revascularisations, hospitalisations, HRQoL

**Source of funding** | NR

**Conflicts of interest** | None declared

**Notes** | Authors contacted for further clinical outcomes and QoL data but no response received

**Risk of bias**

| Bias | Authors' judgement | Support for judgement |

Bäck 2008

Study characteristics

Methods

- **Study design:** single-centre RCT
- **Country:** Sweden
- **Dates participants recruited:** 2004 to 2006
- **Maximum follow-up:** 8 months (6 months following PCI)

Participants

- **Inclusion criteria:** coronary artery stenosis documented by angiography or previous coronary artery bypass grafting, classes I-III angina pectoris, classified according to Canadian Cardiovascular Society.
- **Exclusion criteria:** disabling disease that hindered regular exercise, or if the individual has already engaged in exercise more than 3 days/week
- **N randomised:** total: 37; intervention: 21; comparator: 16
- **Diagnosis (% of participants):** stable CAD: 100%
- **Age (years):** 63.6 years; intervention: 61.5 (59.8 to 65.5); comparator: 64 (58.5 to 71.0)
- **Percentage male:** 86.5%; intervention: 81.0%; comparator: 93.8%
- **Ethnicity:** NR

Interventions

- **Intervention:** participants were asked to exercise at home on a bicycle ergometer for 30 min (including a 10-minute warm-up and a 5-minute cool-down), 5 days a week for 8 months. The training programme was initiated 2 months before the PCI. Twice a week the training participants were allowed to exchange cycling for an equivalent exercise such as jogging or swimming.
- **Components:** exercise and education
- **Setting:** home
- **Exercise programme modality:** bicycle ergometer
- **Length of session:** 30 min
- **Frequency:** 5 times a week.
- **Intensity:** 70% of V0₂ max.
- **Resistance training included?** Resistance exercise with elastic bands, 3 times a week
Bäck 2008 (Continued)

**Total duration:** 8 months

**Co-interventions:** participants in both groups were invited to participate in the CR care consisting of group-based lifestyle education and aerobic as well as resistance exercise twice a week during months 4 to 6.

**Comparator:** usual care

**Co-interventions:** as above

</table>

**Inclusion criteria:** successful procedure of coronary angioplasty in 1 or 2 native epicardial coronary arteries and ability to exercise

**Exclusion criteria:** previous coronary artery procedures, cardiogenic shock, unsuccessful angioplasty (defined as residual stenosis > 30% of initial value), complex ventricular arrhythmias, uncontrolled hy-
pertension and diabetes mellitus, creatinine > 2.5 mg/dL, orthopedic or neurological limitations to exercise or unstable angina after procedure and before enrolment

**N randomised:** total:118; intervention: 59; comparator: 59

**Diagnosis (% of participants):**
- Myocardial infarction: intervention: 51; comparator: 47
- Hypercholesterolemia: intervention: 61; comparator: 54
- Diabetes: intervention: 17; comparator: 20
- Hypertension: intervention: 42; comparator: 47
- LVEF (%): intervention: 52 (SD 16); comparator: 50 (SD 14)
- **Age (mean ± SD):** intervention: 53 ± 11; comparator: 59 ± 10
- **Percentage male:** intervention: 83.1%; comparator: 84.8%
- **Percentage white:** NR

### Interventions

**Intervention:** exercise sessions were performed at the hospital gym and were supervised by a cardiologist. After a 15-min phase of stretching and calisthenics, participants pedaled on an electronically-braked cycle ergometer at the target work rate for 30 min. This working phase was preceded by a 5-min loadless warm-up and followed by 3 min of unloaded cool-down pedaling.

**Components:** exercise only

**Setting:** supervised in hospital gym

**Exercise programme modality:** electronically-braked cycle ergometer

**Length of session:** 53 min.

**Frequency:** 3 sessions/week

**Intensity:** 60% of peak oxygen uptake (VO\textsubscript{2})

**Resistance training included?** Yes - calisthenics

**Total duration:** six months

**Co-interventions:** none described

**Comparator:** control participants were recommended to perform basic daily mild physical activities but to avoid any physical training. A list of acceptable physical activities was provided, together with a diary to report daily activities.

**Co-interventions:** none described

### Outcomes

Cardiac mortality; myocardial infarction; coronary angioplasty (percutaneous transluminal coronary angioplasty, coronary stent); coronary artery bypass graft; health-related quality of life: MOS Short-Form General Health Survey

**Source of funding**

NR

171 participants were randomised and at discharge, the cardiologist decided whether the participant was fit to take part in the rehabilitation programme - 45 participants were excluded at this point. Seven people in the intervention group declined to take part, but six of these were seen at follow-up and included in the analysis because "control group probably had a comparable number who would have declined further treatment."

### Bertie 1992

#### Study characteristics

- **Methods**: Study design: single-centre RCT; participants were randomised on day of discharge after MI  
  - Country: UK  
  - Dates participants recruited: NR  
  - Maximum follow-up: 24 months

- **Participants**: Inclusion criteria: men and women with AMI  
  - Exclusion criteria: uncontrolled heart failure; serious rhythm disturbances which persisted and required treatment at time of discharge; another disabling disease  
  - N randomised: total: 110; intervention: 57; comparator: 53  
  - Diagnosis (% of participants): AMI: 100%  
  - Age (mean ± SD): intervention: 52.1 ± 1.3; comparator: 52.7 ± 1.3
Interventions

**Exercise**: a formal rehabilitation programme at the hospital started 3 weeks post-discharge. The programme concentrated mainly on standard pulse-monitored group exercise, supervised by a physiotherapist. Participants completed a circuit of 12 exercises, and after a five-minute interval, they repeated the circuit, up to a maximum of four circuits.

**Components**: exercise

**Setting**: supervised group sessions in the hospital gymnasium

**Exercise programme modality**: "group exercises"

**Length of session**: NR

**Frequency**: twice per week

**Intensity**: NR

**Total duration**: 4 weeks

**Co-interventions**: health, smoking and dietary advice and a relaxation technique

**Comparator**: standard hospital care

**Co-interventions**: all participants were asked to stop smoking and given dietary advice either for weight reduction or because of elevated serum cholesterol. To boost confidence, each participant was asked to walk up two flights of stairs under supervision and was given advice on mobilisation on discharge.

Outcomes

**Total mortality, non-fatal MI, revascularisation; assessments at day of discharge, 3rd week after discharge; after rehabilitation (for intervention group); four months after infarct and 12 to 24 months after infarct**

Source of funding

NR

Conflicts of interest

### Bethell 1990

#### Study characteristics

**Methods**
- **Study design:** single-centre RCT
- **Country:** UK
- **Dates participants recruited:** 1 December 1979 to March 1984
- **Maximum follow-up:** 5 years

**Participants**
- **Inclusion criteria:** < 65 years post MI; history of chest pain typical of MI, progressive ECG changes, rise and fall in aspartate transaminase concentrations with at least one reading above 40 units/mL
- **Exclusion criteria:** medical or orthopaedic problems that precluded their taking part in the exercise course; insulin-dependent diabetes mellitus; atrial fibrillation; on investigator’s personal general practice list
- **N randomised:** total: 200; intervention: 99; comparator: 101
- **Diagnosis (% of participants):** MI: 100%
- **Age (mean ± SD):** intervention: 54.2 ± 7.2; comparator: 54.2 ± 7.2
- **Percentage male:** intervention: 100%; comparator: 100%
- **Ethnicity:** NR

**Interventions**
- **Intervention:** treatment participants entered a three-month course of three times a week circuit training.
  - **Components:** exercise only
  - **Setting:** centre
  - **Exercise programme modality:** 8 stage circuit aerobic training
  - **Length of session:** NR
  - **Frequency:** 3 times a week
  - **Intensity:** 70% to 85% predicted HR max.
  - **Resistance training included?** Yes - weight training
  - **Total duration:** 3 months
  - **Co-interventions:** NR
- **Comparator:** participants were given a short talk on the sort of exercise that they might safely take unsupervised
  - **Co-interventions:** NR

**Outcomes**
- **Total mortality, CHD mortality, non-fatal MI**
  
  (11 year follow-up published in 1999. Five-year follow-up data from unpublished material used for meta analysis.)

**Source of funding**
- British Heart Foundation and Wessex Regional Health Authority

**Conflicts of interest**
- NR

**Notes**
- 229 participants were randomised; 14 in the intervention group and 15 in control dropped out before the first exercise test due to death, refusal or other problems. Therefore 200 took part in the study.
Cardiac mortality of 3% per annum, once participants survived to be in the trial. Suggests more severely affected participants were not included. Significant predictors of cardiac death were pulmonary oedema on admission, complications during admission, one or more previous infarcts, increasing age and low initial fitness.

**Bettencourt 2005a**

**Study characteristics**

**Methods**

- **Study design:** single-centre RCT (1:3 randomisation)
- **Country:** Portugal
- **Dates participants recruited:** 1 September 2001 to 31 December 2002
- **Maximum follow-up:** 1 year

**Participants**

- **Inclusion criteria:** participants without previous cardiological follow-up, with > 4 years' education, following hospitalisation for acute coronary syndrome (ACS)
- **Exclusion criteria:** none stated
- **N randomised:** total: 126; intervention: 31; comparator: 95
- **Diagnosis (% of participants):**
  - Unstable angina: intervention 20; comparator: 27
  - Non-Q wave MI: intervention 33; comparator: 31
  - Anterior MI: intervention 23; comparator: 20
  - Inferior MI: intervention 24; comparator: 21
  - MI of undetermined location: intervention 10; comparator 11
- **Age (years):** intervention: 56 (range: 31-80); comparator: 58 (range: 33-86)
- **Percentage male:** intervention: 84 %; comparator 83%
**Interventions**

**Intervention:** the sessions took place in the hospital’s gymnasium under qualified supervision. They consisted of a warm-up period at the beginning of each session, 20 to 30 minutes on a treadmill or ergometric bicycle and a recovery period with low intensity activities. The exercise programme was initially based on the maximum heart rate reached on the exercise test prior to beginning the programme (performed on average five weeks after the ACS).

**Components:** exercise only

**Setting:** aerobic exercise in supervised group sessions

**Exercise programme modality:** treadmill and bicycle

**Length of session:** 60 minutes

**Frequency:** 3 times/week

**Intensity:** NR

**Resistance training included?** No

**Total duration:** 12 weeks, followed by one session a month for the remainder of the year

**Co-interventions:** none described

**Comparator:** standard follow-up consisting of a mean of 3.5 consultations per year following the first event

**Co-interventions:** none described

**Outcomes**

HRQoL

## Study characteristics

### Methods

**Study design:** multicentre open RCT (2 sites)

**Country:** Australia

**Dates participants recruited:** 2-year period. No dates given.

**Maximum follow-up:** 1 year

### Participants

**Inclusion criteria:** uncomplicated acute myocardial infarction (AMI) or recovery from unstable angina aged under 75 years, self-caring, adequately literate in the English language, residing in the geographical area of the health service

**Exclusion criteria:** presentation with uncompensated heart failure, uncontrolled arrhythmias, severe and symptomatic aortic stenosis, or other conditions precluding physical activity

**N randomised:** total: 113; intervention: 57; comparator: 56

**Diagnosis (% of participants):**

- AMI: intervention 36.8; comparator 48.2
- Unstable angina: intervention 63.2; comparator 51.8
- Thrombolytic therapy: intervention 14.0; comparator 25.0
- PCI/CAGS: intervention 59.6; comparator 46.4
- Prior AMI, PCI, CAGS: intervention 36.8; comparator 50.0

**Age (Mean ± SD):** intervention: 60.8 ± 8.7; comparator: 61.9 ± 9.4

**Percentage male:** intervention 72%; comparator 75%

**Ethnicity:** NR

### Interventions

**Intervention:** comprehensive exercise-based outpatient cardiac rehabilitation

**Components:** exercise plus education plus psychosocial counselling

**Setting:** hospital-based, supervised exercise

**Exercise programme modality:** aerobic circuit training interspaced with resistance training

**Length of session:** 60 to 90 minutes

**Frequency:** 3 times per week

**Intensity:** NR

**Resistance training included?** Yes

**Total duration:** 6 weeks

**Co-interventions:** 45 minutes of education (12 occasions) and 45 minutes of psychosocial counselling (6 occasions). If necessary, additional one-on-one counselling was provided.

**Comparator:** conventional care: participants from both groups received individualised medical treatment including non-invasive and invasive cardiological procedures, surgical revascularisation, pharmacotherapy, and lifestyle counselling, as determined by their usual doctors.

**Co-interventions:** none described ("Access to community cardiac rehabilitation programs was limited for the conventional management group")

### Outcomes

Costs, HRQoL

## Bubnova 2019

### Study characteristics

#### Methods

- **Study design:** single-centre RCT
- **Country:** Russia
- **Dates participants recruited:** NR
- **Maximum follow-up:** 12 months.

#### Participants

- **Inclusion criteria:** male and female participants of working age (male < 60 years, female < 55 years) with acute MI (3 to 8 weeks prior), signed informed consent to participate, absence of generally accepted contraindications to performing exercise training
- **Exclusion criteria:** left ventricular aneurysm with thrombosis, stroke, serious disturbances in the rhythm and conduction of the heart, uncontrolled arterial hypertension with blood pressure ≥ 180/100 mmHg, NYHA class III-IV heart failure, thromboemboli, aortic aneurysm, history of syncope, thrombophlebitis, phlebothrombosis, musculoskeletal disorders, moderate to severe diabetes, severe concomitant diseases, chronic respiratory, hepatic or renal failure
- **N randomised:** total: 300; intervention: 155; comparator: 145. Groups then split into 3 subgroups according to rehabilitation potential (intervention: low n = 32, average n = 55, high n = 68; control: low n = 22, average n = 64, high n = 59)
- **Diagnosis (% of participants):** 100% acute MI (68% STEMI)
- **Age (mean ±SD):** intervention: 49.9 ± 7.2; comparator 50.9 ± 6.1
**Bubnova 2019 (Continued)**

**Percentage male:** intervention: 93.5%, comparator: 92.4%

**Ethnicity:** NR

**Interventions**

**Intervention:** physical rehabilitation classes consisting of gymnastics exercises carried out for 60 minutes in groups under supervision of a cardiologist 3 times per week for 1 year.

**Components:** exercise only

**Setting:** centre-based

**Exercise programme modality:** gymnastic exercises

**Length of session:** 1 hour

**Frequency:** three sessions per week

**Intensity:** not reported

**Resistance training included?** No

**Total duration:** 1 year

Byrkjeland 2015

Study characteristics

Methods

- **Study design:** single-centre RCT
- **Country:** Norway
- **Dates participants recruited:** August 2010 to March 2012
- **Maximum follow-up:** 12 months

Participants

- **Inclusion criteria:** type 2 diabetes and verified CAD by angiography
- **Exclusion criteria:** presence of proliferative retinopathy, end-stage renal disease, cancer, stroke or acute MI within the last 3 months, unstable angina, uncompensated heart failure, serious arrhythmia, severe valvular disease, severe rheumatologic disease, chronic obstructive pulmonary disease (COPD) stage IV, thromboembolic disease, ongoing infections, severe musculoskeletal disorders and other disabilities limiting the ability for physical activity

  - **N randomised:** total: 137; intervention: 69; comparator: 68
  - **Diagnosis (% of participants):** stable angina 51 (37%); previous MI 62 (45%).
  - **Age (mean ±SD):** intervention: 64.6 ± 7.9; comparator: 63.2 ± 7.2
  - **Percentage male:** intervention: 45 (87%); comparator: 50 (81%)
  - **Ethnicity:** NR

Interventions

- **Intervention:** 12-month combined aerobic and resistance training programme
- **Components:** exercise only
- **Setting:** both centre- and home-based
- **Exercise programme modality:** circuits containing aerobic and resistance exercises, interval uphill walking/running training, interval step training, spinning on a bike
- **Length of session:** 1 hour
- **Frequency:** three sessions per week (2 supervised centre-based, 1 home-based)
### Study characteristics

**Methods**

- **Study design**: multicentre RCT (3 sites)
- **Country**: Italy
- **Dates participants recruited**: January 2017 to April 2018
- **Maximum follow-up**: 12 months

**Participants**

- **Inclusion criteria**: age ≥ 70 years, hospital admission for ACS, short physical performance battery (SPPB) score from 4 to 9 at the inclusion visit (30 ± 5 days after discharge)
Exclusion criteria: participants with SPPB score ≥ 10 or ≤ 3. Multivessel disease with indication for surgical revascularisation or staged PCI, inability to be discharged to home, congestive HF, LVEF < 30%, severe valvular disease

N randomised: total: 235; intervention: 118; comparator: 117

Diagnosis (% of participants): intervention: STEMI 33 (28%), NSTEMI 75 (65%), unstable angina 10 (7%); comparator: STEMI 31 (26%), NSTEMI 77 (66%), unstable angina 9 (8%)

Age (median, range): intervention: 76, 72 to 80; comparator: 77, 73 to 80

Percentage male: intervention: 92 (78%); comparator: 89 (76%)

Ethnicity (White, %): NR

Interventions

Intervention: 4 supervised sessions (1, 2, 3, 4 months after discharge) combined with an individualised home-based exercise programme. Centre-based sessions supervised by sports physician and nurse, and included moderate treadmill walk, strength and balance exercises (30 to 40 min). Participants received a walking programme to perform at home along with a selection of calisthenic exercises based on the Otago Exercise Programme. Participants encouraged to perform exercises 2 times per week for approx 20 mins. After the 4 month supervised session, a long-term home-based exercise programme was designed by the sports physician.

Components: exercise only

Setting: 4 centre-based sessions, home-based afterwards

Exercise programme modality: walking, calisthenics, strength and balance

Length of session: 30 to 60 minutes

Frequency: at least 3 to 4 times per week

Intensity: RPE 11 to 13

Resistance training included? No

Total duration: 6 months

Co-interventions: health education

Comparator: standard of care

Co-interventions: health education – 15 minute visit with study doctor, who explained the importance of aerobic physical activity (30 to 60 min/day, moderate intensity, e.g. brisk walking for at least 3 days/week). A detailed brochure explaining the benefits of physical exercise provided to all participants.

Outcomes

Total and cardiovascular mortality, ACS, hospitalisations, HRQoL

Source of funding

"Investigator-driven clinical trial conducted by the University of Ferrara"

Conflicts of interest

None declared

Notes

None

## Carlsson 1998

### Study characteristics

**Methods**

- **Study design**: single-centre RCT
- **Country**: Sweden
- **Dates participants recruited**: NR
- **Maximum follow-up**: 1 year

**Participants**

- **Inclusion criteria**: AMI; CABG < 2 weeks prior; PCI < 2 weeks prior
- **Exclusion criteria**: signs of unstable angina; signs of ST-depression at exercise test of more than 3 mm in 2 chest leads or more than 2 mm in two limb leads at four weeks post-discharge from hospital, signs of CHF, severe, non-cardiac disease; drinking problems, not a Swedish speaker
- **N randomised**: total: 235; intervention: 118; comparator: 117
- **Diagnosis (% of participants)**: CABG: 25%; AMI: 75%
- **Age (mean ± SD)**:
  - AMI patients: intervention: 62.2 ± 5.8; comparator: 61.7 ± 6
  - CABG patients: intervention: 62.7 ± 4.8; comparator: 59.8 ± 4.8
- **Percentage male**: NR
- **Ethnicity**: NR

**Interventions**

- **Intervention**: continuous physical exercise programme 2 to 3 times weekly for 2 to 3 months. The exercise sessions lasted one hour and were comprised of the following parts: 10 minutes of warm-up; 40 minutes of interval walking or jogging; 10 minute cool-down period (consisting of relaxation and light stretching exercises). Individual exercise schedules were provided in order to maintain the effects of the exercise programme beyond the discharge from the hospital training centre.
- **Components**: exercise plus education
- **Setting**: centre and then home
- **Exercise programme modality**: walking or jogging
- **Length of session**: 60 minutes
### Carlsson 1998 (Continued)

**Frequency:** 2 to 3 times/week  
**Intensity:** NR  
**Resistance training included?** No  

**Total duration:** 2 to 3 months  
**Co-interventions:** 9 hours of nurse counselling in individual and group sessions over 1 year; smoking cessation 1.5 hours, dietary management 5.5 hours  
**Comparator:** usual care, which included two or three visits to their general practitioners during the first year  

**Co-interventions:** all participants were informed about CAD risk factors and the effect of lifestyle changes on the prognosis.

### Carson 1982

#### Study characteristics

- **Study design:** single-centre RCT; participants randomised 6 weeks post-admission  
- **Country:** UK  
- **Dates participants recruited:** NR (recruited over a 3.5 year period)
### Maximum follow-up

3 years

### Participants

**Inclusion criteria:** MI; diagnosis based on ECG changes and/or elevation of serum glutamic oxaloacetic transaminase or lactic dehydrogenase taken on three consecutive days.

**Exclusion criteria:** > 70 years; heart failure at follow-up clinic; cardio-thoracic ratio exceeding 59%; severe chronic obstructive lung disease; hypertension requiring treatment; diabetes requiring insulin; disabling angina during convalescence; orthopaedic or medical disorders likely to impede progress in the gym, personality disorders likely to render participant unsuitable for the course.

**N randomised:** total: 303; intervention: 151; comparator: 152

**Diagnosis (% of participants):** MI: 100%

**Age (mean ± SE):** intervention: 50.3 ± 0.65; comparator: 52.8 ± 0.67

**Percentage male:** intervention: 100%; comparator: 100%

**Ethnicity:** NR

### Interventions

**Intervention:** participants attended the hospital gym twice weekly for 12 weeks. They were supervised by a doctor and physical educationalist and full resuscitative equipment was available. The exercises were arranged on a circuit basis and pure isometric exercise was avoided.

**Components:** exercise only

**Setting:** centre

**Exercise programme modality:** exercises arranged on a circuit basis

**Length of session:** NR

**Frequency:** twice per week

**Intensity:** NR

**Resistance training included?** No

**Total duration:** 12 weeks

**Co-interventions:** none described

**Comparator:** did not attend gym

**Co-interventions:** none described

### Outcomes

Total mortality, non-fatal MI at 5 months, 1 year, 2 years and 3 years after MI (mean follow-up 2.1 years)

### Source of funding

Department for Health and Social Security Grant

### Conflicts of interest

NR

### Notes

There appears to be a reduction in mortality in exercise participants with inferior MI.

**Chaves 2019**

**Study characteristics**

**Methods**

**Study design:** superiority RCT with waiting-list control (single centre)  
**Country:** Brazil  
**Dates participants recruited:** March 2015 to April 2017  
**Maximum follow-up:** 12 months - 6 months waiting-list control

**Participants**

**Inclusion criteria:** participants aged > 18 years and living in the Belo Horizonte area, with coronary artery disease: post myocardial infarction undergone percutaneous coronary intervention or coronary artery bypass graft surgery and had been referred to CR  
**Exclusion criteria:** cardiac conditions associated with some risk during high-intensity exercise (e.g. heart failure with EF < 45%, complex ventricular dysrhythmia), any comorbid physical condition (e.g. leg amputation, advanced cancer, disabling stroke, Parkinson’s disease), or serious mental illness that would interfere with the ability to exercise, according to CR clinical practice guidelines, or any visual or cognitive condition that would preclude the participant from completing the questionnaires

**N randomised:** total: 115; intervention 1 (exercise only): 39; intervention 2 (comprehensive CR): 37; comparator: 39

**Diagnosis (% of participants):** participants with CAD after MI or those undergoing PCI/CABG. MI 107 (93%), angina 69 (60%), PCI 68 (59.1%), CABG 29 (25.5%).

**Age (mean):** intervention 1: 59 ± 9.9; intervention 2: 60.7 ± 8.8; comparator: no CR (n = 16) 55.9± 6.7, exercise only (n = 12) 60.7 ± 13.3, comprehensive CR (n = 11) 60.6 ± 8.4

**Percentage male:** intervention 1: 28 (71.8%); intervention 2: 27 (73%); comparator: no CR (n = 16) 11 (68.8%), exercise only (n = 12) 12 (100%), comprehensive CR (n = 11) 4 (36.4%)

**Ethnicity (white, %):** NR

**Interventions**

**Intervention:** CR program led by a physician and staffed by physiotherapists. Exercise programme 6 months, consisting of 36 1-hour supervised sessions descending in frequency. Participants provided individualised exercise prescription based on exercise test. Participants requested to exercise in their communities on non-centre-based exercise days to accumulated ≥ 30 minutes of MVPA on ≥ 5 days per week.

Comprehensive CR participants were offered an additional 24, weekly 30-minute education sessions, delivered in groups by a health educator, and received a validated education workbook to accompany the sessions.

**Components:** exercise only (group 1); exercise plus education (group 2)

**Setting:** centre-based (with request to complete home-based exercise in addition)

**Exercise programme modality:** treadmill/bike/walking
Chaves 2019 (Continued)

**Length of session:** 1 hour  
**Frequency:** 3 times per week for 4 weeks, 2 times per week for 4 weeks, once per week for 16 weeks.  
**Intensity:** 50% to 80% heart rate reserve  
**Resistance training included?** NR  

**Total duration:** 6 months

**Co-interventions:** education sessions provided for comprehensive CR group (group 2). Educational curriculum included: information about the CR program, their aerobic exercise prescription and safety, managing angina, irregular heartbeats, diabetes, exercising in cold and hot weather, the heart (anatomy, pathophysiology, diagnoses, and treatment) and cardiac medications risk factor profile, goal setting and action planning, resistance training, nutrition (fats, fibre, reading food labels, sodium), psychosocial risk, and sexual intimacy, how much physical activity is good, aerobic and resistance training progression, relapse planning, and graduation.

**Comparator:** waiting-list control – all participants received follow-up appointments with their physician as deemed medically important. Participants in the control arm received CR after 6-month mortality ascertained. Participants elected whether they wanted to have exercise only or comprehensive CR, or no CR.

**Co-interventions:** none

### Outcomes

Cardiovascular mortality, MI, revascularisations, hospitalisations

### Source of funding

Professor Britto was supported by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq no. 305786/2014-8), Fundacao de Amparo a Pesquisa do Estado de Minas Gerais (FAPEMIG no. PPM-00869-15 and CS00290-16) and Coordination for the Improvement of Higher Education Personnel (CAPES)

### Conflicts of interest

None declared

### Notes

Outcomes at 6 months only used for this review, as waiting-list control participants elected which arm of the study to go into after this point.

## Study characteristics

### Methods

**Study design:** multicentre RCT (5 sites); participants were randomised 3rd day post MI  
**Country:** USA  
**Dates participants recruited:** NR  
**Maximum follow-up:** 12 months

### Participants

**Inclusion criteria:** men and women aged 70 years or younger who were hospitalised for AMI.  
**Exclusion criteria:** none described  
**N randomised:** total: 585; intervention: 293; comparator: 292  
**Diagnosis (% of participants):** MI: 100%  
**Age (mean):** intervention: 57 ± 8; comparator: 57 ± 8  
**Percentage male:** intervention: 78.5%; comparator: 79.1%  
**Ethnicity (white, %):** intervention: 78.0%; comparator: 75.9%

### Interventions

**Intervention:** the exercise prescription was based on a heart rate range corresponding to 60% to 85% of the peak heart rate achieved during treadmill testing. Participants were instructed to exercise at the prescribed heart rate for 30 minutes per day 5 days per week. Participants walked briskly, jogged, rode a bicycle, or swam. After 4 weeks, the ceiling of the heart-rate training range was raised to 100% of the peak treadmill exercise heart rate or 85% of the age-predicted max HR.  
**Components:** exercise plus education  
**Setting:** nurse-managed, home-based  
**Exercise programme modality:** walking, jogging, cycling or swimming  
**Length of session:** 30 minutes per day  
**Frequency:** 5 days per week  
**Intensity:** 60% to 85% of the peak heart rate achieved during treadmill testing, then raised to 100%  
**Resistance training included?** No  
**Total duration:** 12 months  
**Co-interventions:** all medically eligible participants received exercise training; all smokers received the smoking cessation intervention; and all participants received dietary counselling and, if needed, lipid-lowering drug therapy  
**Comparator:** usual care including physician counselling on smoking cessation, nutritionist counselling on dietary change during hospitalisation, and physician-managed, lipid-lowering drug therapy after hospital discharge  
**Co-interventions:** group outpatient smoking cessation programmes were available for a $50 fee. Group exercise rehabilitation, not generally provided, was available to participants at various community facilities at an average cost of $1800 to $2700 for 3 months' participation.

### Outcomes

**Total mortality**

### Source of funding

Grant support: By HL38874 from the National Heart, Lung, and Blood Institute, Bethesda, Maryland and a Shannon Award from the National Institutes of Health, Bethesda, Maryland. Dr. Thomas participated as a Clinical Scholar of the Robert Wood Johnson Foundation.

### Conflicts of interest

NR
### DeBusk 1994 (Continued)

**Notes**
Levels of psychological distress dropped significantly for both groups by 12 months.

### Dorje 2019

#### Study characteristics

**Methods**
- **Study design**: single-centre RCT
- **Country**: China
- **Dates participants recruited**: November 2016 to March 2017
- **Maximum follow-up**: 12 months.

**Participants**
- **Inclusion criteria**: participants aged 18 or older with documented coronary heart disease (including MI and unstable or stable angina) who were treated with PCI during their index admission. Participants were required to own an operational smartphone, have an active WeChat account or be willing to create one and have sufficient Chinese language proficiency to enable communication with the cardiac rehabilitation and secondary prevention coach via WeChat.
- **Exclusion criteria**: contraindications to exercise rehabilitation, an inability to operate a smartphone for the purpose of the trial (e.g. vision, hearing, and cognitive or dexterity impairment), no internet access at their place of residence, or pre-existing comorbid disease with a life expectancy less than 1 year.
- **N randomised**: total: 312; intervention: 156; comparator: 156
- **Diagnosis (% of participants)**: post PCI (100%)
- **Age (mean)**: intervention: 61.9 ± 8.7; comparator: 59.1 ± 9.4
- **Percentage male**: intervention: 126 (81%); comparator: 128 (82%)
- **Ethnicity (white, %)**: NR

**Interventions**
- **Intervention**: smartphone-based home cardiac rehabilitation delivered via WeChat platform. Included a simplified and culturally sensitive WeChat based education programme addressing coronary heart disease knowledge and awareness.
Exercise component: individualised walking programme based on baseline 6MWT, with time and intensity of walking increased gradually over the first 8 weeks.

Physical activity monitored using WeChat’s inbuilt pedometer function to monitor step counts, along with a WeChat interfaced blood pressure and heart rate monitor.

Support provided for medication adherence and risk factor modification (dietary change, lipid control, smoking cessation) provided as required by participants.

Data readings automatically transmitted to a secure data portal and reviewed by cardiac rehabilitation coach on a regular basis and provided individualised feedback.

**Components:** exercise plus education

**Setting:** Home-based

**Exercise programme modality:** walking

**Length of session:** NR

**Frequency:** at least 5 times per week

**Intensity:** NR

**Resistance training included?** No

**Total duration:** 6 months

**Co-interventions:** none described

**Comparator:** standard care as provided by their community doctors and cardiologists. Typically involves brief inpatient health education provided by a ward nurse, medication management and ad-hoc follow-up visits to a cardiologist or health care provider according to the participant’s self-assessment of their own cardiovascular health

**Co-interventions:** none described

**Outcomes**

| HRQoL, adverse cardiac events |

**Source of funding**

Curtin University

**Conflicts of interest**

None declared

**Notes**

**Risk of bias**

### Dugmore 1999

**Study characteristics**

| Methods | Study design: single-centre RCT  
Country: UK  
Dates participants recruited: between 1984 and 1988  
Maximum follow-up: 5 years |
|---------|---------------------------------------------------------------|
| Participants | **Inclusion criteria:** MI according to conventional WHO cardiac enzyme and ECG criteria of MI  
**Exclusion criteria:** NR  
**N randomised:** total: 124; intervention: 62; comparator: 62  
**Diagnosis (% of participants):** MI: 100%  
**Age (years):** intervention: 54.8; comparator: 55.7  
**Percentage male:** 98% intervention: NR; comparator: NR  
**Ethnicity:** NR |
| Interventions | **Intervention:** participants received regular aerobic and local muscular endurance training three times a week for 12 months. This consisted of warm-up and cool-down exercises, sit ups, wall bar/bench step ups, cycle ergometry, and a major component centred on the training of aerobic capacity, using walking and jogging. Training programmes were individually designed and based on the results of regular exercise tests and trial exercise prescriptions.  
**Components:** exercise only  
**Setting:** centre  
**Exercise programme modality:** walking, jogging and cycle ergometry  
**Length of session:** individually designed  
**Frequency:** 3 times a week  
**Intensity:** varied between approx 50% to 65% of measured peak oxygen uptake (VO\(_2\)) in the poor prognosis participants and 65% to 80% of peak VO\(_2\) in those with a good prognosis  
**Resistance training included?** Yes - local muscular endurance training  
**Total duration:** 12 months  
**Co-interventions:** none described.  
**Comparator:** received no formal exercise training throughout the same 12-month period  
**Co-interventions:** none described |
**Dugmore 1999 (Continued)**

**Outcomes**
CV mortality; non-fatal MI; HRQL at 4, 8, 12 months

**Source of funding**
NR

**Conflicts of interest**
NR

**Notes**
The population was subdivided into groups with good and bad prognoses. There were 36 participants with a good prognosis and 26 with a poor prognosis. Each group were matched with control participants.

**Engblom 1996**

**Study characteristics**

**Methods**

- **Study design**: single-centre open RCT
- **Country**: Finland
- **Dates participants recruited**: February 1986 to December 1987
- **Maximum follow-up**: 5 years

**Participants**

- **Inclusion criteria**: participants who underwent elective CABG
- **Exclusion criteria**: any other serious disease; > 65 years of age
- **N randomised**: total: 228; intervention: 119; comparator: 109
- **Diagnosis (% of participants)**:
  - Previous unstable angina: intervention: 29; comparator: 31
  - Previous MI: intervention: 42; comparator: 46
  - Hypertension: intervention: 31; comparator: 23
  - LVEF: intervention: 70.3; comparator: 71.4
Age (mean ± SD): intervention: 54.1 ± 5.9; comparator: 54.3 ± 6.2

Percentage male: 88%

Ethnicity: NR

Interventions

**Intervention:** 6 to 8 weeks after the CABG, participants followed a 3-week general CR program, mainly based on exercises, including 24 hours of supervised activities consisting of ergometer cycle training, ball games, outdoor activities, gymnastics and swimming. The participants were also advised to increase their physical activity in leisure time.

**Components:** exercise and education

**Setting:** supervised group sessions at centre

**Exercise programme modality:** ergometer cycle training, ball games, outdoor activities, gymnastics and swimming

**Length of session:** NR

**Frequency:** NR

**Intensity:** NR

**Resistance training included?** NR

**Total duration:** 3 weeks (plus an additional 5 days over a 30-month period)

**Co-interventions:** participants participated in a 4-stage CR programme over 30 months, including dietary counselling and advice about the importance of healthy nutrition and economical cooking.

**Comparator:** all of the participants in both groups received standard postoperative care which consisted of visits to the cardiac outpatient clinic 2, 6, 12, 24, 36 and 60 months after the CABG

**Co-interventions:** none described

Outcomes

Mortality, CABG, HRQoL: Nottingham Health Profile

Source of funding

Grants from the Sauli Viikari Fund within the Cultural Foundation of Varsinais-Suomi, Turku, Finland

Conflicts of interest

NR

Notes

Five years after CABG, only 20% of participants were working, despite 90% of participants being in functional classes 1-2. Almost half of participants had retired pre-CABG. Many other factors affect return to work post-CABG - age, education, physical requirements of the job, type of occupation, self-employed status, non-work income, personality type, self-perception of working capacity and mostly length of absence from work pre-CABG.

### Erdman 1986

#### Study characteristics

**Methods**
- **Study design:** single-centre RCT
- **Country:** the Netherlands
- **Dates participants recruited:** September 1976 to March 1978
- **Maximum follow-up:** 5 years

**Participants**
- **Inclusion criteria:** first MI within 6 months before the first psychological investigation; < 65 years; meet three psychological inclusion criteria - one or more symptoms of the anxiety reaction, diminished self-esteem, positive motivation to take part in the programme
- **Exclusion criteria:** severe cardiomyopathy, severe valvular disorders, inadequate performance on exercise, unstable angina pectoris
- **N randomised:** total: 80; intervention: 40; comparator: 40
- **Diagnosis (% of participants):** MI: 100%
- **Age (years):** 51 years (range 35 to 60 years); intervention: NR; comparator: NR
- **Percentage male:** intervention: 100%; comparator: 100%
- **Ethnicity:** NR

**Interventions**
- **Intervention:** two 1½ hour sessions of fitness training a week in a conventional gymnasium, supervised by a cardiologist. Each session consisted of a 15-min warm-up, gymnastics and jogging (both 15 min); sport such as volleyball, soccer and hockey (30 min), and relation exercises (15 min).
  - **Components:** exercise and education
  - **Setting:** supervised group sessions in centre
  - **Exercise programme modality:** gymnastics, jogging and team sports
  - **Length of session:** 90 min
  - **Frequency:** twice a week.
  - **Intensity:** NR
  - **Resistance training included?** No
  - **Total duration:** 6 months
- **Co-interventions:** in cases of severe psychopathology, a psychologist or a psychiatrist was consulted.
- **Comparator:** home rehabilitation - participants received an educational brochure with guidelines and advice about physical fitness training and jogging.
- **Co-interventions:** treatment with either beta blockers or anticoagulants was given upon indication only and not as a prophylactic measure.

**Outcomes**
- **Mortality, non-fatal MI at 5 years**

**Source of funding**
- Dutch Heart Foundation
### Erdman 1986 (Continued)

#### Conflicts of interest

NR

#### Notes

Complex presentation of results. Authors conclude that participants who will benefit from rehabilitation can be detected on psychological grounds. Those who have engaged in habitual exercise, but feel seriously disabled, yet do not feel inhibited in a group, will benefit from rehab.

### Fletcher 1994

#### Study characteristics

**Methods**

**Study design:** single-centre RCT  
**Country:** USA  
**Dates participants recruited:** NR  
**Maximum follow-up:** 6 months

**Participants**

**Inclusion criteria:** ≤ 73 years; CAD and physical disability. CAD documented by history of MI, coronary artery bypass surgery, PCI or angiographically demonstrated CAD; have the functional use of more than 2 extremities, 1 being an arm, in order to perform the exercise test and training protocols.

**Exclusion criteria:** uncontrolled hypertension or diabetes mellitus, clinically significant cardiac dysrhythmias, unstable angina pectoris, cognitive deficits, or other problems that would interfere with compliance to the prescribed exercise and diet protocol.

**N randomised:** total: 88; intervention: 41; comparator: 47  
**Diagnosis (% of participants):** CAD and a physical disability  
**Age (mean ±SD):** intervention: 62 ± 8; comparator: 63 ± 7  
**Percentage male:** intervention: 100%; comparator: 100%  
**Ethnicity:** NR
Interventions

Intervention: participants were provided with a wheelchair ramp with rollers and a telephone electrocardiographic recording device. They were instructed to exercise using the ramp which essentially transformed their wheelchair into a stationary wheelchair ergometer. Specific instructions were to exercise 5 days/week for 20 minutes a day for a total of 100 minutes each week.

Components: exercise plus education

Setting: home

Exercise programme modality: stationary wheelchair ergometer

Length of session: 20 min

Frequency: 5 days/week

Intensity: 85% of predicted maximal heart rate

Resistance training included? No

Total duration: 6 months

Co-interventions: both groups received didactic and written dietary instruction from a registered dietitian on the American Heart Association Step I low-cholesterol, low-saturated fat diet.

Comparator: usual care

Co-interventions: participants in the control group received dietary instruction and were instructed to follow activity guidelines provided by their primary physician and health care team.

Outcomes

Total mortality, non-fatal MI at 6 months

Source of funding

United States Department of Education

Conflicts of interest

NR

Notes

The treatment programme decreased myocardial oxygen demand.

Fridlund 1991

Study characteristics

Exercise-based cardiac rehabilitation for coronary heart disease (Review)
Methods

Study design: single-centre RCT

Country: Sweden

Dates participants recruited: September 1985 to March 1988

Maximum follow-up: 5 years

Participants

Inclusion criteria: 65 years or younger at the time of MI; independent living in the Health Care District after discharge from hospital; meaningful communication and rehabilitation that was not hindered by the MI or other serious illness

Exclusion criteria: cerebral or cardiac disorders or serious alcohol abuse

N randomised: total: 178; intervention: 87; comparator: 91

Diagnosis (% of participants):

MI: 100%
Angina: intervention: 32.1%; comparator: 33.3%

Age (years): intervention: 55; comparator: 57.6

Percentage male: 87% intervention: 86.8%; comparator: 87.3%

Ethnicity: NR

Interventions

Intervention: participants and their spouses visited the hospital for a 2-hour group session each week for 6 months. These group sessions consisted of a physical and a psychosocial part and were carried out together with a support team consisting of a physiotherapist, a physician and a rehabilitation nurse. The physical part consisted of both exercise and relaxation.

Components: exercise plus psychosocial support

Setting: centre

Exercise programme modality: NR
Length of session: 2 hrs
Frequency: once a week
Intensity: NR
Resistance training included? NR

Total duration: 6 months

Co-interventions: the psychosocial part contained eleven themes concerning lifestyle and risks after MI, and psychosocial consequences of MI

Comparator: routine cardiac follow-up

Co-interventions: none described

Outcomes

Total mortality, non-fatal MI, revascularisations

Source of funding

Swedish Heart Lung Foundation, National Association for Heart and Lung Patients, Sweden, and the County Council, Halland, Sweden

Conflicts of interest

NR

Notes

Positive long-term effects on physical condition, life habits, cardiac health knowledge. No effects found for cardiac events or psychological condition.

Risk of bias

### Giallauria 2008

#### Study characteristics

**Methods**
- **Study design:** single-centre RCT
- **Country:** Italy
- **Dates participants recruited:** NR
- **Maximum follow-up:** 6 months

**Participants**
- **Inclusion criteria:** acute ST elevation MI
- **Exclusion criteria:** residual myocardial ischaemia, severe ventricular arrhythmias, AV block, valvular disease requiring surgery, pericarditis, severe renal dysfunction (creatinine > 2.5 mg/dL)
- **N randomised:** total: 61; intervention: 30; comparator: 31
- **Diagnosis (% of participants):** MI: 100%
- **Age (mean ±SD):** intervention: 55.9 ± 3.1; comparator: 55.1 ± 3.7
- **Percentage male:** intervention: 73%; comparator: 71%
- **Ethnicity:** NR

**Interventions**
- **Intervention:** training sessions were supervised under continuous electrocardiography monitoring. Each session was preceded by a 5-min warm-up and followed by a 5-min cool-down. Exercise was performed for 30 min on a bicycle ergometer with the target of 60% to 70% of VO\textsubscript{2} peak achieved at the initial symptom-limited cardiopulmonary exercise test. Exercise workload was gradually increased until the achievement of the predefined target.
- **Components:** exercise only
- **Setting:** supervised in centre
- **Exercise programme modality:** bicycle ergometer
- **Length of session:** 40 min
- **Frequency:** 3 times a week
### Giallauria 2008 (Continued)

**Intensity:** target of 60% to 70% of VO$_2$ peak achieved at the initial symptom-limited cardiopulmonary exercise test  
**Resistance training included?** No  
**Total duration:** 6 months  
**Co-interventions:** none described  
**Comparator:** discharged with generic instructions on maintaining physical activity and a correct lifestyle  
**Co-interventions:** none described

### Hambrecht 2004

**Study characteristics**

**Methods**  
**Study design:** single-centre RCT  
**Country:** Germany  
**Dates participants recruited:** March 1997 to March 2001  
**Maximum follow-up:** 1 year

**Participants**  
**Inclusion criteria:** angina pectoris according to Canadian Cardiovascular Society class I–III, with documented myocardial ischaemia during stress-electrocardiogram and/or 99mTc scintigraphy and amenable to PCI. Only participants living within a 25 km radius of the host institution were recruited.
**Exclusion criteria:** acute coronary syndromes or recent myocardial infarction (< 2 months); left main coronary artery stenosis > 25%; reduced left ventricular function (ejection fraction < 40%); significant valvular heart disease; insulin-dependent diabetes mellitus; previous coronary artery bypass graft or PCI; and conditions excluding regular exercise

**N randomised:** total: 101; intervention: 51; comparator: 50

**Diagnosis (% of participants):**
- Stable CAD: 100%
- (class I to III angina pectoris)

**Age (years ± SEM):**
- Intervention: 62 ± 1
- Comparator: 60 ± 1

**Percentage male:** 100%

**Ethnicity:** NR

**Interventions**

**Intervention:** during the first 2 weeks, participants exercised in the hospital 6 times/day for 10 min on a bicycle ergometer at 70% of the symptom-limited max HR. Before discharge, a maximal symptom-limited ergospirometry was performed to calculate the target heart rate for home training, which was defined as 70% of the maximal heart rate during symptom-limited exercise. Participants were asked to exercise on their bicycle ergometer close to the target heart rate for 20 min per day and to participate in one 60 min group training session of aerobic exercise/week.

**Components:** exercise only

**Setting:** supervised exercise in hospital, followed by unsupervised at home plus weekly group training

**Exercise programme modality:** bicycle ergometer

**Length of session:** 10 minutes

**Frequency:** 6 times a day.

**Intensity:** 70% of symptom-limited max heart rate

**Resistance training included?** No

**Total duration:** 2 weeks, followed by 20 min per day unsupervised at 70% plus 60 min aerobic group training per week

**Co-interventions:** all participants were recommended to receive acetylsalicylic acid, β-blockers, angiotensin-converting enzyme inhibitors and statins according to common guidelines.

**Comparator:** stent angioplasty: “the target lesion was treated with PCI after a bolus of 10,000 IU of heparin with a 6F guiding catheter.”

**Co-interventions:** all participants were given acetylsalicylic acid 100 mg/d and clopidogrel 300 mg/d on the day before the procedure.

**Outcomes**

Clinical symptoms, angina-free exercise capacity, myocardial perfusion, cost-effectiveness, and frequency of a combined clinical end point (death of cardiac cause, stroke, CABG, angioplasty, acute myocardial infarction, and worsening angina with objective evidence resulting in hospitalisation)

**Source of funding**

“This study was supported by an unconditional scientific grant from Aventis Germany”.

**Conflicts of interest**

NR

**Notes**

2 year results of this study are reported by Walther 2008.

### Haskell 1994

#### Study characteristics

**Methods**

- **Study design:** multicentre RCT (4 sites)
- **Country:** USA
- **Dates participants recruited:** February 1984 to March 1987
- **Maximum follow-up:** 4 years

**Participants**

- **Inclusion criteria:** men and women < 75 years of age with clinically-indicated coronary arteriography who lived within a 5-hour drive of Stanford University and considered capable of following the study protocol. After arteriography, participants received PCI or CABG and remained eligible if at least one major coronary artery had a segment with lumen narrowing between 5% and 69% that was unaffected by revascularisation procedures.
- **Exclusion criteria:** severe congestive heart failure, pulmonary disease, intermittent claudication, or non-cardiac life-threatening illnesses; no qualifying segments, medical complication occurred during angiography, left ventricular ejection fraction of less than 20%, or participant was in another research study
- **N randomised:** total: 300; intervention: 145; comparator: 155
- **Diagnosis (% of participants):** CHD: 100%
- **Age (mean ± SD):** intervention: 58.3 ± 9.2; comparator: 56.2 ± 8.2
- **Percentage male:** 86%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** a physical activity programme consisting of an increase in daily activities such as walking, climbing stairs and household chores, and a specific endurance exercise training programme* with the exercise intensity based on the subject’s treadmill exercise test performance.
- **Components:** exercise plus education
- **Setting:** home
**Exercise programme modality:** stationary cycling or walking  
**Length of session:** 30 min  
**Frequency:** 5 days a week.  
**Intensity:** 70% to 85% of the peak heart rate attained on exercise testing at 3 weeks, an average of 96 to 121 beats/min  
**Resistance training included?** No  
**Total duration:** NR  
**Co-interventions:** each risk-reduction participant met with a nurse to design an individualised risk-reduction programme based on the participant’s risk profile, his or her motivation, and resources for making specific changes. Participants were instructed by a dietitian in a low-fat, low-cholesterol, and high-carbohydrate diet with a goal of < 20% of energy intake from fat, < 6% from saturated fat, and < 75 mg of cholesterol per day. Current or recent ex-smokers were provided with an individualised stop-smoking or relapse-prevention programme by a staff psychologist.  
**Comparator:** usual care  
**Co-interventions:** none described  

### Outcomes  
Total and CHD mortality, non-fatal MI, revascularisation at year 1, 2, 3 and 4  

### Source of funding  
National Heart, Lung, and Blood Institute and a gift from the Claude R. Lambe Charitable Foundation. Lipid drugs for participants in the risk reduction group provided by the Upjohn Company, Merck & Company, and Parke-Davis, Inc.  

### Conflicts of interest  
NR  

### Notes  
*This exercise programme followed guidelines developed previously for home-based exercise training of cardiac patients (Miller 1984).*  
The rate of change in the minimal coronary artery diameter was 47% less in intervention than comparator. This was still significant when adjusted for age and baseline segment diameter ($P = 0.03$).

### Hautala 2017

#### Study characteristics

**Methods**

- **Study design**: single-centre RCT
- **Country**: Finland
- **Dates participants recruited**: February 2011 to May 2014
- **Maximum follow-up**: 12 months

**Participants**

- **Inclusion criteria**: CAD patients who suffered from acute coronary syndrome, with coronary angiography to confirm the CAD.
- **Exclusion criteria**: NYHA class ≥ III, scheduled or emergency procedure for bypass surgery, unstable angina pectoris, severe peripheral atherosclerosis, diabetic retinopathy or neuropathy, or inability to perform regular home-based exercises, for example, due to severe musculo-skeletal problems
- **N randomised**: total: 204; intervention: 109; comparator: 95
- **Diagnosis (% of participants)**: intervention: NSTEMI 47 (48%); STEMI 44 (45%); comparator: NSTEMI 45 (58%); STEMI 28 (36%)
- **Age (mean)**: intervention: 60 ± 11; comparator: 62 ± 9
- **Percentage male**: intervention: 80 (73%); comparator: 67 (71%)
- **Ethnicity (white, %)**: NR

**Interventions**

- **Intervention**: the 1-year exercise training intervention consisted of home-based aerobic (30 to 40 min) and gym-based strength exercises (30 to 40 min).
  - On the first two visits to the gym, participants were provided instruction on use of the gym, a home-based exercise training program for the first month, how to fill in the exercise training diary, use of the RPE scale to evaluate the average intensity of a single exercise session, a schedule for gym visits, and use of an accelerometer. Thereafter, the participants exercised in the gym once per week for 6 months in groups of no more than eight participants.
  - A wrist-worn accelerometer was provided to improve motivation and adherence. Participants instructed to continuously wear the accelerometer and monitor their own daily PA.
  - After 6 months, home-based exercise continued and checkpoint visits to monitor progression of exercise training were scheduled at 9 and 12 months.
Components: exercise plus other components such as dietary counselling or check-up by a medical doctor when appropriate.

Setting: both centre and home (1 centre-based resistance training session per week for 6 months).

Exercise programme modality: walking, running, cycling or cross-country skiing
Length of session: 30 to 40 minutes
Frequency: 4 to 5 per week
Intensity: RPE 12-15 (aerobic), RPE 13 (resistance)

Resistance training included? Yes - strength exercise circuit targeted at major muscle groups at moderate intensity (2-3 X 7 sets, ≥ 10 repetitions/set) RPE 13.

Total duration: 1 year

Co-interventions: None described

Comparator: usual care – participants did not receive any individually-tailored exercise prescriptions.

Co-interventions: none described

Outcomes
Mortality, hospitalisations, HRQoL, cost effectiveness

Source of funding
NR

Conflicts of interest
JMA is a partner of ESIOR Oy, which provides health economic and outcome research services to pharmaceutical and medical device companies. The other authors report no conflicts of interest.

Notes
Authors provided further data relating to clinical outcomes and HRQoL.

He 2020

Study characteristics

Methods
Study design: single-centre RCT
Country: China
Dates participants recruited: August 2014 to October 2016

Maximum follow-up: 3 years

Participants

Inclusion criteria: (1) fulfilling Third Universal Definition of Myocardial Infarction criteria; (2) a coronary angiography that show no artery stenosis ≥ 50% in any infarct-related artery; (3) no other clinically overt cause or account for the acute presentation

Exclusion criteria: (1) sepsis, cardiac contusion, pulmonary embolism, overlooked obstructive coronary artery disease (CAD), coronary embol or thrombus, Takotsubo syndrome, and myocarditis; (2) limited exercise tolerance (ejection fraction <35%, chronic obstructive pulmonary disease with FEV1 <50%, severe anaemia); (3) age ≥ 75 years old; (4) physical disability or mental confusion; (5) individuals refused to participate in the trial

N randomised: total: 524; intervention: 262; comparator: 262

Diagnosis (% of participants): 100% MI with PCI

Age (mean ±SD): intervention: 60.6 ± 12.7; comparator 60.9 ± 12.9

Percentage male: intervention: 45.8%, comparator: 47.7%

Ethnicity: NR

Interventions

Intervention: participants exercised 3x per week in the hospital for 20 to 30 min on a treadmill or bicycle at 65% to 75% of symptom limited maximal heart rate. After discharge, moderate continuous training was performed – cycling or treadmill running continuously at a moderate intensity (65% to 75% max HR) for 47 mins 3x per week. Participants used MI electronic band to monitor heart rate and physicians used WeChat software to instruct and supervise individuals each month during the follow-up period. The home-based program consisted of 52 exercise sessions (3x per week) each year.

Components: exercise only

Setting: centre- and home-based

Exercise programme modality: treadmill walking/running or cycling

Length of session: 20 to 30 minutes increasing to 47 minutes

Frequency: three sessions per week

Intensity: 65% to 75% of the symptom limited heart rate max

Resistance training included? No

Total duration: 3 years

Co-interventions: none described

Comparator: control participants did not receive CR

Co-interventions: none described

Outcomes

MACE at 3 years, HRQoL at 1 year

Source of funding

Supported by Zhejiang Provincial Science Foundation of China under Grant No. LY20H020006 and Zhejiang Provincial Basic Public Welfare Research Program of China under Grant No. LGF19H020007

Conflicts of interest

None declared

Notes

Authors emailed to request further data (mortality, MI, hospitalisation) but no response

### Heller 1993

#### Study characteristics

**Methods**

**Study design:** cluster-randomised multicentre RCT  
**Country:** Australia  
**Dates participants recruited:** 18 September 1990 to 5 December 1991  
**Maximum follow-up:** 6 months

**Participants**

**Inclusion criteria:** < 70 years with a suspected heart attack registered by the Newcastle collaborating centre of the WHO MONICA Project and discharged alive from hospital  
**Exclusion criteria:** renal failure or other special dietary requirements and those considered by their physicians to have ‘endstage’ heart disease  
**N randomised:** total: 450; intervention: 213; comparator: 237  
**Diagnosis (% of participants):** MI: 100%  
**Age (mean ± SD):** intervention: 59 ± 8; comparator: 58 ± 8  
**Percentage male:** 71%  
**Ethnicity:** NR

**Interventions**

**Intervention:** a mail-out programme designed to help participants reduce dietary fat, obtain regular exercise by walking and to quit smoking.  
- 1st package: Step 1 "Facts on fat" kit, together with walking programme information, encouragement to walk in the form of a magnetic reminder sticker, and "Quit for Life" programme for smokers.  
- 2nd package: Steps 2-3 "Facts on fat" kit; exercise log.  
- 3rd package: Steps 4-5 "Facts on fat" kit, together with information regarding local "Walking for Pleasure" groups.  
**Components:** exercise plus education
Setting: home

Exercise programme modality: walking
Length of session: NR
Frequency: NR
Intensity: NR
Resistance training included? NR

Total duration: 6 months.

Co-interventions: supplementary telephone contact was also used and a letter was sent to the family doctor regarding the benefit of aspirin and β blockers for secondary prevention.

Comparator: usual care

Co-interventions: none described

Outcomes

Total mortality, HRQL
Study outcomes assessed at 6 months

Source of funding
National Health and Medical Research Council of Australia

Conflicts of interest
NR

Notes
Low use of preventative services (dietary, anti smoking) by both groups
10% of participants received CR - mostly having had CABG

Higgins 2001

Study characteristics

Methods

Study design: single-centre RCT

Country: Australia
**Participants**

- **Inclusion criteria:** participants scheduled for PCI
- **Exclusion criteria:** major co-morbidity such as malignancy, a history of cerebrovascular accident, or other severe, chronic debilitating disease; previous CABG or peri-PCI complications; unemployment in previous year; MI within 1 month pre-procedure; surgical management at home time during the 1 year duration of study.
- **N randomised:** total: 105; intervention: 54; comparator: 51
- **Diagnosis (% of participants):**
  - Previous MI: intervention: 52%; comparator: 51%
  - Previous PCI: intervention: 10%; comparator: 16%
- **Age (years):** intervention: 48 (range 31 to 63); comparator: 47 (range 26 to 63)
- **Percentage male:** intervention: 83%; comparator: 96%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** individualised comprehensive CR programme based on the principles of social cognitive theory involved a moderate-intensity walking programme with a graded increase in the frequency and duration of exercise. In the 2 months post-PCI, the clinician made 3 home visits to each participant and went walking with them as part of this visit. In addition, during home visits, participants were taught to monitor their rate of perceived exertion (RPE) during their walking programme and to document the frequency, duration and RPE of those sessions in an exercise log.
- **Components:** exercise plus psychological plus education
- **Setting:** home
- **Exercise programme modality:** walking
- **Length of session:** not specified – goal setting was based on personalised risk-factor profiles
- **Frequency:** NR
- **Intensity:** NR
- **Resistance training included?** No
- **Total duration:** not specified

**Co-interventions:** the intervention group received the same education sessions as the control group as well as an individualised, comprehensive CR program based on the principles of social cognitive theory. Strategies used to modify risk factors included (1) goal setting, (2) self-monitoring and feedback, (3) skills training, (4) reinforcement of target behaviours, and (5) the provision of social support by the clinician. Vocational counselling included specific recommendations regarding return to work. The clinician also made monthly calls when she provided counselling and guidance.

- **Comparator:** whilst hospitalised, control participants received two, one-to-one bedside education sessions; one 45 min session pre-PCI and one 60 min session post-PCI. Teaching media included videotapes of the procedure, photographs of coronary anatomy during the procedure, and equipment. Post-PCI education included providing information about the pathology and risk factors for CHD and instruction on wound and medication management.

**Co-interventions:** the clinician made 3 monthly post-discharge CHD information-focused telephone calls to each control participant.

**Outcomes**

- **Mortality**

**Source of funding**

"Prince Charles Hospital Private Practice Fund supported the research"
### Study characteristics

#### Methods

- **Study design:** single-centre RCT  
- **Country:** Sweden  
- **Dates participants recruited:** February 1993 to December 1995  
- **Maximum follow-up:** 2 years

#### Participants

- **Inclusion criteria:** (a) at least one significant stenosis suitable for PTCA and at least one additional - although clinically non-significant - stenosis or plaque, measurable with quantitative computerised angiography (QCA); (b) age < 65 years; (c) employed; (d) absence of other diseases of importance for the programme or with poor prognosis; and (e) able to perform a bicycle ergometer test with a minimum exercise capacity of 70 watts.  
- **Exclusion criteria:** none described  
- **N randomised:** total: 87; intervention: 46; comparator: 41  
- **Diagnosis (% of participants):** treated with percutaneous transluminal angioplasty  
- **Age (mean):** intervention: 53; comparator: 53  
- **Percentage male:** 83.9%  
- **Ethnicity:** NR

#### Interventions

- **Intervention:** started with a 4-week residential stay at the intervention unit. The programme included intense health education and activities promoting behavioural changes - stress management, diet, ex-
Exercise and smoking habits. Each subject was assigned a daily individual task including self-observation, Type A behavioural drills, relaxation training and exercise. Followed by 11-month structured maintenance programme.

**Components:** exercise plus psychological plus education

**Setting:** centre followed by home

**Exercise programme modality:** NR

**Length of session:** NR

**Frequency:** NR

**Intensity:** NR

**Resistance training included?** NR

**Total duration:** 12 months

**Co-interventions:** maintenance programme consisted of continuous self-observation and self-recording of important everyday lifestyle behaviours, feedback of behaviour changes, and of regular follow-up contacts between the participant and his/her personal coach for verbal feedback, problem-solving, and replanning discussions when needed.

**Comparator:** standard care

**Co-interventions:** none described

### Study characteristics

#### Methods

**Study design:** single-centre RCT  
**Country:** Sweden  
**Dates participants recruited:** "during a 2-year period"  
**Maximum follow-up:** 1 year

#### Participants

**Inclusion criteria:** acute MI patients under 65 years of age  
**Exclusion criteria:** not stated, but individuals have been excluded for being incapable of performing strenuous training due to poor left ventricular function or arrhythmias, orthopaedic disorders, other incapacitating somatic diseases or mental disorders.  
**N randomised:** total: 69; intervention: 34; comparator: 35  
**Diagnosis (% of participants):** post-MI: 100%  
**Age (mean years [range]):** intervention: 55 (38 to 65); comparator: 55 (43 to 63)  
**Percentage male:** 97%  
**Ethnicity:** NR

#### Interventions

**Intervention:** started 8 weeks post-MI and participants trained over a 12-week period for at least 45 minutes (effective time) twice a week with interval training involving large muscle groups: bicycling (10 min), callisthenics (10 min), jogging (15 min) ending with relaxation (10 min).  
**Components:** exercise only  
**Setting:** not described, but assumed in a centre  
**Exercise programme modality:** bicycling 10 mins, callisthenics 10 min, jogging  
**Length of session:** at least 45 mins  
**Frequency:** twice per week.  
**Intensity:** 70% to 85% of peak heart at the bicycle test for initial session and workload individually adjusted to obtain the desired maximum heart rate if possible  
**Resistance training included?** Yes - callisthenics  
**Total duration:** 12 weeks  
**Co-interventions:** none described  
**Comparator:** received regular medical care with no emphasis on exercise  
**Co-interventions:** none described

#### Outcomes

Total mortality, non-fatal MI & revascularisation  
Health-related quality of life: self-report questionnaire  
Evaluations at 6 weeks and 1 year post-MI

#### Source of funding

Research support was given by Malmöhus County Council

#### Conflicts of interest

NR

#### Notes

Study authors found no benefit from exercise training. Outcomes were related to self-rated levels of physical and psychological well being.

**Holmback 1994 (Continued)**

**Study characteristics**

**Methods**
- **Study design:** multicentre RCT (2 sites)
- **Country:** Canada
- **Dates participants recruited:** April 2007 to April 2008
- **Maximum follow-up:** 12 months

**Participants**

- **Inclusion criteria:** participants hospitalised for an ACS (unstable angina, non-ST-elevation or ST elevation myocardial infarction) and willing to travel to the CR centre every 3 months to meet the clinical nurse specialist and able to read and speak French
- **Exclusion criteria:** inability to perform activities of daily living (such as feeding themselves, bathing, dressing, grooming, work, homemaking and leisure); enrolment in another research project or in a heart failure clinic where serial follow-up creates a bias and contraindication to exercise testing; medical diagnosis of debilitating chronic illness (such as cancer without remission), musculoskeletal or neurological disorder (such as multiple sclerosis, Parkinson’s disease, etc.); people with a previous history of stroke could be included if they had no residual effects related to their stroke; serious and unstable mental incapacities or major depression
- **N randomised:** total: 65; intervention: 32; comparator: 33
- **Diagnosis (% of participants):**
  - Unstable angina: intervention: 50%; comparator: 52%
  - STeMI: intervention: 28%; comparator: 27%
  - Non STeMI: intervention: 22%; comparator: 21%
- **Age (mean ± SD):** intervention: 58 ± 8; comparator: 59 ± 9
- **Percentage male:** total: 78%; intervention: 81%; comparator: 76%
- **Ethnicity:** NR
### Interventions

**Intervention:** participants received a pedometer-based programme concomitantly with a socio-cognitive intervention led by a clinical nurse specialist. Participants used 1 pedometer blinded and used a second one to monitor their daily steps since discharge.

**Components:** exercise plus education plus socio-cognitive intervention

**Setting:** home

**Exercise programme modality:** walking

**Length of session:** not specified

**Frequency:** not specified

**Intensity:** not specified

**Resistance training included?** No

**Total duration:** 12 months

**Co-interventions:** participants received a socio-cognitive intervention led by a clinical nurse specialist, and a blinded pedometer with instructions about how to wear the pedometer correctly during 7 consecutive days from morning to bedtime.

**Comparator:** participants received the usual advice by the nurse or the physician, or both, at discharge regarding physical activity, diet and medication. They had no restriction to go to a centre-based cardiac rehabilitation programme or to consult a health care professional such as a nutritionist, an exercise specialist or a psychologist. Participants in both groups received usual medical follow-up by their own physicians (cardiologist and family physician).

**Co-interventions:** participants received a blinded pedometer and instructions about how to wear the pedometer correctly during 7 consecutive days from morning to bedtime.

### Outcomes

**HRQoL**

### Source of funding

Heart and Stroke Foundation of Canada, Research centre of Institut Universitaire de Cardiologie et Pneumologie de Québec, and Pfizer Canada

### Study characteristics

#### Methods
- **Study design:** multicentre RCT (2 sites)
- **Country:** Finland
- **Dates participants recruited:** May 1973 to October 1975
- **Maximum follow-up:** 3 years

#### Participants
- **Inclusion criteria:** participants treated in hospital for acute myocardial infarction based on WHO criteria
- **Exclusion criteria:** NR
- **N randomised:** total: 375; intervention: 188; comparator: 187
- **Diagnosis (% of participants):** AMI: 100%
- **Age (mean):** intervention: 54.4; comparator: 54.1
- **Percentage male:** 80.3%
- **Ethnicity:** NR

#### Interventions
- **Intervention:** the programme was started two weeks after discharge from hospital and consisted of medical examinations by an internist at least monthly for the first six months after AMI, then when necessary or at least 3-monthly. A physical exercise programme, tailored to the individual’s working capacity determined in a bicycle ergometer test, was recommended, and for most participants, it was done under supervision. The rehabilitation programme was most intensive during the first three months after myocardial infarction.
- **Components:** exercise, education and psychological
- **Setting:** supervised in a centre
- **Exercise programme modality:** NR
- **Length of session:** NR
- **Frequency:** NR
- **Intensity:** NR
- **Resistance training included?** NR
- **Total duration:** NR
- **Co-interventions:** besides the internist, the team included a social worker, a psychologist, a dietitian, and a physiotherapist. Health education consisted of anti-smoking and dietary advice, and discussions on psychosocial problems.
- **Comparator:** usual care
- **Co-interventions:** none described

#### Outcomes
- **Total mortality; cardiovascular mortality (follow-up 3 years).**

#### Source of funding
- **Social Insurance Institution**

#### Conflicts of interest
- NR

#### Notes
- NR

#### Study characteristics

**Methods**

- **Study design:** multicentre RCT (2 sites)
- **Country:** Australia
- **Dates participants recruited:** NR
- **Maximum follow-up:** 6 months

**Participants**

- **Inclusion criteria:** AMI; < 75 years of age; no angina; < 2 mm ST-segment depression with exercise and if they attained > 7-METS workload; left ventricular ejection fraction > 40% or no inducible ventricular tachycardia
- **Exclusion criteria:** participants were excluded if there was 2 mm ST-segment depression with exercise or if 7-METS workload was attained.
- **N randomised:** total: 142; intervention: 70; comparator: 72
- **Diagnosis (% of participants):** AMI: 100%
- **Age (mean):** intervention: 56.2; comparator: 55.8
- **Percentage male:** intervention: 89%; comparator: 86%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** exercise (conventional treatment group): 5 week rehabilitation program consisted of exercise, education and counselling sessions that were held 2 to 4 times per week, including work at 6 weeks after AMI.
- **Components:** exercise, education and psychological
- **Setting:** NR
- **Exercise programme modality:** NR
**Kovoor 2006** (Continued)

**Length of session:** NR  
**Frequency:** 2 to 4 times per week  
**Intensity:** NR  
**Resistance training included?** NR

**Total duration:** 5 weeks

**Co-interventions:** the 2 groups of participants were encouraged to exercise at home on a regular basis. Participants were given the telephone numbers of the cardiologist and the nurse co-ordinator so they could be contacted in case of problems.

**Comparator:** control group (ERNA - early return to normal activities group): return to work at 2 weeks after AMI without a formal CR programme.

**Co-interventions:** this group of participants was contacted over the telephone by the nurse co-ordinator once per week for 5 weeks. The 2 groups were encouraged to exercise at home on a regular basis. Participants were given the telephone numbers of the cardiologist and the nurse co-ordinator so they could be contacted in case of problems.

**Outcomes**

Total mortality; fatal/non-fatal mortality; CAGB; PCI; HRQoL. Costs reported in Hall 2002.

Assessment at 6 weeks and at 6 months

**Source of funding**

National Health and Medical Research Council, Sydney, Australia

**La Rovere 2002**

**Study characteristics**

**Methods**

**Study design:** single-centre RCT

**Country:** Italy
### Participants
- **Inclusion criteria:** post-MI patients admitted at Centro Medico di Montescano in 1984 to 1985
- **Exclusion criteria:** atrial fibrillation or abnormal sinus node function, insulin-dependent diabetes, exercise-induced myocardial ischaemia, and arterial BP > 160/90
- **N randomised:** total: 95; intervention: 49; comparator: 46
- **Diagnosis (% of participants):** uncomplicated MI: 100%
- **Age (mean):** intervention: 51; comparator: 52
- **Percentage male:** 100%
- **Ethnicity:** NR

### Interventions
- **Intervention:** the exercise sessions (30 minutes, 5 times a week) consisted of callisthenics and stationary bicycle ergometry
- **Components:** exercise, education and psychological
- **Setting:** supervised in a centre
- **Exercise programme modality:** stationary bicycle ergometry
- **Length of session:** 30 minutes
- **Frequency:** 5 times a week
- **Intensity:** 75% of heart rate at peak VO2, rising to 85% in the second and third weeks and 95% in the final week
- **Resistance training included?** Yes - callisthenics
- **Total duration:** 4 weeks
- **Co-interventions:** sessions were held by cardiologists and psychologists, dealing with secondary prevention of cardiovascular disease and stressing dietary changes and smoking cessation.
- **Comparator:** no training
- **Co-interventions:** all participants attended sessions, held by a cardiologist and a psychologist, dealing with secondary prevention of cardiovascular disease and stressing dietary changes and smoking cessation.

### Outcomes
- Cardiac mortality; non-fatal MI; CABG at 3 to 4 month intervals from the time of entry into the study for the first 3 years and contacted periodically by telephone thereafter.

### Source of funding
- NR

### Conflicts of interest
- NR

### Notes

<tr>
<td><strong>Intervention:</strong> web-based virtual cardiac rehabilitation program.</td>
</tr>
<tr>
<td>30-minute in-person training session on the use of the virtual CR program. Participants supplied with heart rate monitor and blood pressure monitor.</td>
</tr>
<tr>
<td>Virtual CR program included online intake forms (medical, risk factor and lifestyle), scheduled one on one chat sessions with the program nurse or case manager, exercise specialist and dietician (3 times each during 12 weeks), weekly education sessions with interactive slide presentations, data capture for exercise stress test and blood test results, progress notes and monthly <code>ask an expert</code> group chat sessions.</td>
</tr>
</tbody>
</table>
The home-page displayed the tasks that needed to be completed for each week. Participants were asked to wear heart rate monitor whilst exercising and upload exercise data at least twice per week into the system.

**Components:** exercise plus education

**Setting:** home-based

**Exercise programme modality:** NR

**Length of session:** NR

**Frequency:** NR

**Intensity:** NR

**Resistance training included?** NR

**Total duration:** 16 weeks

**Co-interventions:** none described

**Comparator:** usual care (care from primary care physician); participants were given simple guidelines for safe exercising and healthy eating habits and a list of internet-based resources.

**Co-interventions:** none described

### Outcomes

Cardiovascular-related emergency room and major events

### Source of funding

Heart and Stroke Foundation of BC and Yukon and in part by Canada Health Infoway. Dr Lear holds the Pfizer/Heart and Stroke Foundation Chair in Cardiovascular Prevention Research at St. Paul’s Hospital.

### Conflicts of interest

None declared

### Notes

Authors contacted for specific clinical outcomes, but no response received.

**Study characteristics**

### Methods
- **Study design**: multicentre RCT (4 sites)
- **Country**: France
- **Dates participants recruited**: February 1981 to May 1984
- **Maximum follow-up**: 2 years

### Participants
- **Inclusion criteria**: admitted to participating coronary care units with suspected MI; < 65 years old with typical MI, no major irreversible complication or disability
- **Exclusion criteria**: contraindication to exercise testing; i.e. recent stroke, disability of lower limbs, uncontrolled heart failure, severe rhythm disturbances, SBP > 180 mmHg, severe angina pectoris, or abnormalities triggered by baseline exercise test.
- **N randomised**: total: 182; intervention: 61; comparator (usual care): 60 counselling programme: 61 (no data analysed in this review)
- **Diagnosis (% of participants)**: MI: 100%
- **Age (mean)**: intervention: 51; comparator: 49
- **Percentage male**: 100%
- **Ethnicity**: NR

### Interventions
- **Intervention**: the programme started within a few days of randomisation and included three training sessions a week on a cycloergometer, walking and gymnastics.
- **Components**: exercise and education
- **Setting**: centre
- **Exercise programme modality**: cycloergometer, walking and gymnastics
- **Length of session**: 25 min
- **Frequency**: 3 times per week
- **Intensity**: 80% of max HR and then decreased progressively over 2 min (increased as the sessions progressed)
- **Resistance training included?**: No
- **Total duration**: 6 weeks
- **Co-interventions**: also included respiratory physiotherapy, relaxation, recommendations on control of cardiovascular risk factors (smoking habits, diet); recommendations to continue regular physical training at the end of the 6-week programme.
- **Comparator**: participants in the usual care group were referred to their usual private practitioner or cardiologist or both.
- **Co-interventions**: None described

### Outcomes
- **Non-fatal MI, angina, surgery**

### Source of funding
- Institut National de la Same et de la Recherche Medicale, by the Hospices Civils de Lyon and by the Association pour la Promotion et la Realisation d’Essais Therapeutiques

### Conflicts of interest
- NR
Leizorovicz 1991 (Continued)

Notes

Only 14% of all MI patients admitted to the participating hospitals were randomised to the trial. Exclusion of women and patients > 65 accounted for 60% of exclusions.

### Study characteristics

#### Methods

<table>
<thead>
<tr>
<th>Study design: single-centre RCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country: Scotland, UK</td>
</tr>
<tr>
<td>Dates participants recruited: March 1988 to March 1991</td>
</tr>
<tr>
<td>Maximum follow-up: 1 year</td>
</tr>
</tbody>
</table>

#### Participants

| Inclusion criteria: confirmed MI (WHO criteria); age less than 80 years; able to speak and read English; resident in the hospital catchment area |
| Exclusion criteria: known history of major psychiatric illness; current psychotic symptoms; evidence of dementia or continuing uncontrolled arrhythmias or heart failure |
| N randomised: total: 176; intervention: 88; comparator: 88 |
| Diagnosis (% of participants): MI: 100% |
| Age (mean ± SD): intervention: 55.3 ± 10.7; comparator: 56.3 ± 10.5 |
| Percentage male: intervention: 70.0%; comparator: 72.7% |
| Ethnicity: NR |

#### Interventions

| Intervention: heart manual consisted of six weekly sections that included education, a home-based exercise programme, and a tape-based relaxation and stress management programme. |
| Components: exercise, education and psychological |
| Setting: home |
Exercise programme modality: NR
Length of session: NR
Frequency: NR
Intensity: NR
Resistance training included? NR

Total duration: 6 weeks.

Co-interventions: specific self-help treatments were provided for psychological problems commonly experienced by post-MI patients. Before the participant was discharged from hospital, spouses were given an audiotape that provided information and advice. After discharge, the facilitator made contact with both groups of participants at 1, 3 and 6 weeks, by telephone, at a hospital clinic, or, when neither of these was possible, by brief home visits.

Comparator: the control group received an equal amount of the facilitator’s time (approximately 10 min).

Co-interventions: participants were given an extensive package of leaflets from various sources, intended to cover the same information as that presented in the manual.

Outcomes
- HRQoL, Hospital Anxiety and Depression Scale (HAD), General Health Questionnaire (GHQ)

Source of funding
This research was supported by a grant from the Chief Scientist Office of the Scottish Home and Health Department. The British Heart Foundation donated additional computer equipment.

Conflicts of interest
NR

Notes
Study terminated (due to expiry of funding) before all participants reached 6-month or 12-month stage. Anxiety scores showed significant treatment effect at 6 weeks and 1 year, depression at 6 weeks. Pre-hospital discharge, 52% of all participants had HAD scores indicating clinically significant anxiety or depression (8+). Control group were significantly more anxious and depressed at all follow-ups.

Ma 2020

Study characteristics
Methods

**Study design:** single-centre RCT

**Country:** China

**Dates participants recruited:** January 2014 to December 2015

**Maximum follow-up:** 36 months (12 month intervention plus 24 month follow-up)

Participants

**Inclusion criteria:** angiographically diagnosed as unprotected left main coronary artery disease (ULM-CAD), and the ‘unprotected’ in this context was defined that no perfusion distal to the left main stenosis was supplied by either a patent bypass graft or a collateral vessel; underwent CABG for the first time; age ≥ 18 years; able to independently fulfil the assessment questionnaires used in the study; likely to be followed up regularly, which was evaluated by the investigators.

**Exclusion criteria:** cardiogenic shock; cerebrovascular accident with a persistent neurological deficit before enrolment; complicated with malignancies; pregnant or lactating women.

**N randomised:** total: 300; intervention: 150; comparator: 150.

**Diagnosis (% of participants):** CABG (100%).

**Age (mean, SD):** intervention: 63.1 ± 9.7; comparator: 62.8 ± 10.7.

**Percentage male:** intervention: 121 (80.7%); comparator: 115 (76.7%).

**Ethnicity (white, %):** NR

Interventions

**Intervention:** Comprehensive rehabilitation and intensive education (CRIE) program consisting of 4 components:

1. CAD-related health education (1/wk for 2 months) – lectures covering basic knowledge of disease, primary therapeutic strategies, risk factors, antiplatelet and anticoagulant therapy, BP management, lipid, glucose, and uric acid, prevention of upper GI mucosal injury, rehabilitation management about exercise, diet and nutrition, psychological care and good lifestyle formation.

2. Exercise guidance and formation (1/month for 10 months) – formulating an individualised exercise plan covering exercise mode: low intensity walking, moderate intensity aerobics (e.g. jogging, gymnastics, tai chi, bicycling), and moderate to high resistance training (e.g. mountain climbing, mid-distance sprint); duration 60 to 90 mins each time; frequency 3 to 5 times per week; intensity: RPE 11 to 13. Monthly supervision and guidance by motivational interviewing.

3. Risk factor control (1/month for 10 months): diet control, alcohol and cigarette cessation, management of blood pressure, lipid, glucose and uric acid. Monthly supervision and guidance by motivational interviewing.

4. Psychological nursing (1/month for 10 months): making a holistic assessment of each participants' physical, functional, psychological, social and spiritual status; identifying potential issues in psychological aspects; eliminating negative emotions and improving compliance; providing music therapy.

**Components:** exercise plus education and psychological nursing

**Setting:** centre-based lectures, with home-based exercise

**Exercise programme modality:** low-intensity walking, moderate-intensity aerobics

**Length of session:** 60 to 90 minutes

**Frequency:** 3 to 5 sessions per week

**Intensity:** RPE 11 to 13

**Resistance training included?** Yes: moderate-high intensity resistance training described as mountain climbing or mid-distance sprinting

**Total duration:** 12 months

**Co-interventions:** none described
Ma 2020 (Continued)

**Comparator:** participants provided discharging guidance and a CAD-related health education manual (same as distributed to intervention group). Provided rehabilitation recommendations and medication consultation through telephone calls or clinic visits according to need.

**Co-interventions:** None described

### Maddison 2014

**Study characteristics**

**Methods**

**Study design:** single-blind multicentre RCT (2 sites)

**Country:** New Zealand

**Dates participants recruited:** 2010 to 2012

**Maximum follow-up:** 24 weeks

**Participants**

**Inclusion criteria:** aged 18 years or more, with a diagnosis of IHD, defined as angina, myocardial infarction, revascularisation, including angioplasty, stent or coronary artery bypass graft within the previous 3 to 24 months. All participants were clinically stable as outpatients, able to perform exercise, able to understand and write English, and had access to the Internet (e.g. at home, work, library or through friends or relatives).

**Exclusion criteria:** participants were excluded if they had been admitted to hospital with heart disease within the previous 6 weeks; had terminal cancer, or had significant exercise limitations other than IHD

**N randomised:** total: 171; intervention: 85; comparator: 86

---

Copyright © 2021 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Diagnosis (% of participants):
- IHD: 100%
- MI: 74%
- Angina: 50%

Age (mean ±SD): total: 60.2 ± 9.3; intervention: 61.4 ± 8.9; comparator: 59.0 ± 9.5

Percentage male: total: 81%; intervention: 81%; comparator: 81%

Ethnicity:
- NZ Maori: total: 8%; intervention: 7%; comparator: 8%
- Pacific: total: 6%; intervention: 6%; comparator: 6%
- Asian: total: 10%; intervention: 9%; comparator: 10%
- NZ European/other: total: 76%; intervention: 78%; comparator: 76%

Interventions

**Intervention:** the HEART programme is a personalised, automated package of text messages via mobile phones aimed at increasing exercise behaviour over 24 weeks. Participants received six messages per week for the first 12 weeks, five messages per week for 6 weeks, and then four messages per week for the remaining 6 weeks.

**Components:** exercise

**Setting:** home

**Exercise programme modality:** moderate to vigorous aerobic-based exercise (e.g. walking and household chores)

**Length of session:** minimum of 30 minutes

**Frequency:** at least 5 days/week.

**Intensity:** NR

**Resistance training included?** No

**Total duration:** 24 weeks

**Co-interventions:** focus on altering the key mediators of behaviour change, including self-efficacy, social support and motivation.

**Comparator:** usual care, with encouragement to be physically active and attend a cardiac club.

**Co-interventions:** all participants were free to participate in any other CR service or support that they wished to use (e.g. participating in community-based CR education sessions on modifying CVD risk factors and psychological support), as well as encouragement to be physically active.

Source of funding

Health Research Council of New Zealand and the Heart Foundation. Dr Maddison was supported by a Heart Foundation Research Fellowship and a Health Research Council Sir Charles Hercus Research Fellowship.

**Manchanda 2000**

**Study characteristics**

**Methods**

- **Study design:** single-centre RCT
- **Country:** India
- **Dates participants recruited:** NR
- **Maximum follow-up:** 1 year

**Participants**

- **Inclusion criteria:** chronic stable angina and angiographically proven CAD
- **Exclusion criteria:** recent (within last six months) MI or unstable angina
- **N randomised:** total: 42; intervention: 21; comparator: 21
- **Diagnosis (% of participants):** chronic stable angina and angiographically proven CAD
- **Age (years):** intervention: 51; comparator: 52
- **Percentage male:** 100%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** participants and their spouses spent four days at a yoga residential centre where they underwent training in various yogic lifestyle techniques. Subsequently they carried out the yogic exercises at home for an average of 90 min daily. The programme included health rejuvenating exercises, breathing exercises, relaxation, meditation, reflection, stress management, dietary control and moderate aerobic exercises.
- **Components:** exercise, education and psychosocial support
- **Setting:** centre followed by home
- **Exercise programme modality:** yoga and "moderate aerobic exercises"
- **Length of session:** 90 min
- **Frequency:** daily
- **Intensity:** NR
- **Resistance training included:** No
- **Total duration:** 1 year
Manchanda 2000  (Continued)

**Co-interventions:** relaxation, reflection, stress management, dietary control

**Comparator:** managed by conventional methods i.e. risk factor control and American Heart Association step I diet.

**Co-interventions:** none described

**Outcomes**
- total mortality; CABG; PCI

Assessments are baseline and 1 year

**Source of funding**
This study was supported in part by a grant from the Central Research Institute of Yoga, Ministry of Health, Government of India.

Marchionni 2003

**Study characteristics**

**Methods**

**Study design:** single-centre RCT

**Country:** Italy

**Dates participants recruited:** NR (48-month period)

**Maximum follow-up:** 14 months

**Participants**

**Inclusion criteria:** > 56 years; referred to unit for functional evaluation 4 to 6 weeks after MI

**Exclusion criteria:** severe cognitive impairment or physical disability, left ventricular EF < 35%, contraindications to vigorous physical exercise, eligibility for myocardial revascularisation because of low-effort myocardial ischaemia, refusal, or living too far from the unit

**N randomised:** total: 270; intervention: 90; home: 90; comparator: 90
Marchionni 2003 (Continued)

**Diagnosis (% of participants):** MI: 100%

**Age (mean [range]):** 69 years [46 to 86]

**Percentage male:** 67.8%

**Ethnicity:** NR

---

**Interventions**

Participants were randomised to outpatient, hospital-based CR (Hosp-CR), home-based CR (Home-CR), or no CR within 3 predefined age groups.

**Intervention:**

Hospital-CR: programme consisted of 40 exercise sessions: 24 sessions (3/wk) of endurance training on cycle ergometer (5-min warm-up, 20-min training at constant workload, 5-min cool-down, 5-min post-exercise monitoring) plus 16 (2/wk) 1-hr sessions of stretching and flexibility exercises.

Home-CR: 4 to 8 supervised instruction sessions in CR unit, where taught how to perform training at home; then participants received exercise prescription similar to Hosp-CR group.

**Setting:** centre or home

**Components:**

Hospital-CR: exercise plus psychosocial support

Home-CR: exercise plus psychosocial support

**Exercise programme modality:** cycle ergometer

**Length of session:** 35 min endurance training; 1 hour stretching and flexibility exercises

**Frequency:** 3 per week of endurance training; 2 per week of stretching and flexibility exercises

**Intensity:** 70% to 85% of heart rate

**Resistance training included?** No

**Total duration:** 8 weeks

**Co-interventions:** participants received cardiovascular risk factor management counselling twice per week and were invited to join a monthly support group together with family members.

**Comparator:** participants randomised to no CR were referred back to their family physicians.

**Co-interventions:** participants received a single structured education session on cardiovascular risk factor management.

---

**Outcomes**

HRQoL at month 2, 8 and 14

### Maroto 2005

**Study characteristics**

**Methods**

- **Study design:** single-centre RCT
- **Country:** Spain
- **Dates participants recruited:** NR (2-year enrolment period)
- **Maximum follow-up:** 10 years

**Participants**

- **Inclusion criteria:** male participants diagnosed with AMI and admitted to the coronary care unit; age < 65 years; low risk (hospital course without complications, absence of signs of myocardial ischaemia, functional capacity > 7 metabolic equivalent time (MET), ejection fraction > 50%, and absence of severe ventricular arrhythmias)
- **Exclusion criteria:** none described
- **N randomised:** total: 180; intervention: 90; comparator: 90
- **Diagnosis (% of participants):**
  - AMI: 100%
  - Anterior: intervention: 40.0%; comparator: 48.3%
  - Inferior/posterior: intervention: 48.3%; comparator: 46.3%
  - Non-Q wave: intervention: 11.6%; comparator: 5.3%
- **Age (mean ± SD):** intervention: 50.3 ± 6; comparator: 52.6 ± 9
- **Percentage male:** 100%
- **Ethnicity:** NR

**Interventions**

- **Intervention:**
  Multidisciplinary CR programme, consisting of:
  - three months supervised, individualised physical training;
  - psychological programme including behavior modification techniques, group therapy, and relaxation sessions;
  - educational programme on modifying lifestyle and controlling coronary risk factors;
  - return to work counselling.
Supervised training was complemented by progressively increasing daily walks of 1 hour in duration, when participants tried to maintain the heart rate achieved during training. Walks were undertaken by participants individually and were unsupervised.

**Components**: exercise plus psychological plus education plus return to work counselling

**Setting**: individualised supervised programme in hospital gym

**Exercise programme modality**: physiotherapy and aerobic training on mats or an exercise bicycle

**Length of session**: 1-hour sessions

**Frequency**: 3 times per week

**Intensity**: 75% to 85% max HR.

**Resistance training included**: No

**Total duration**: 3 months

**Co-interventions**: participants received a psychological programme including behaviour modification techniques, group therapy, and relaxation sessions, an educational programme on modifying lifestyle and controlling coronary risk factors, and return to work counselling.

**Comparator**: participants received conventional treatment

**Co-interventions**: none described

**Outcomes**

- Mortality, MI

**Source of funding**

- NR

**Conflicts of interest**

- NR

**Study characteristics**

**Methods**

**Study design**: RCT; participants randomised 3 weeks post-MI
Country: USA

Dates participants recruited: NR

Maximum follow-up: 6 months

Participants

Inclusion criteria: men < 70 years with MI documented by the combination of characteristic elevation of serum creatine kinase or oxalocatic transaminase, a history of prolonged chest pain consistent with myocardial infarction, and the appearance of new Q waves or evolutionary ST segment changes.

Exclusion criteria: conditions that precluded symptom-limited treadmill testing 3 weeks after infarction. e.g. congestive heart failure, unstable angina pectoris, valvular heart disease, atrial fibrillation, bundle branch block, stroke, limiting orthopedic abnormalities, peripheral vascular disease, chronic obstructive pulmonary disease and obesity, a history of coronary artery bypass graft (CABG) surgery, re-infarction before testing, and intercurrent noncardiac illness.

N randomised: total: 198; group 1: 66; group 2: 61; group 3: 34; comparator: 37

Diagnosis (% of participants): MI: 100%

Age (mean ± SD): 52 ± 9

Percentage male: 100%

Ethnicity: NR

Interventions

Participants were randomly assigned to one of four exercise protocols:

- group 1: 8 to 26 weeks of training at home;
- group 2: training in a group programme;
- group 3: treadmill testing at 3 weeks without subsequent training;
- control: treadmill testing for the first time at 26 weeks.

Regimens of home and group exercise training were designed to provide a similar intensity and duration of exercise training.

Intervention: home training

Components: exercise only

Setting: home

Exercise programme modality: stationary cycling or walking
Length of session: 30 min
Frequency: 5 days a week
Intensity: weeks 3 to 11: 70% to 85% of the peak heart rate at week 3; weeks 11 to 26: 70% to 85% of the peak heart rate at week 11.
Resistance training included? No

Total duration: 8 weeks or 26 weeks.

Co-interventions: none described

Intervention: group training

Components: exercise

Setting: supervised in centre

Exercise programme modality: walking or jogging
Length of session: 1 hour
Frequency: 3 times a week
Intensity: participants regulated their training intensity by palpation of the radial or carotid pulse during the first 10 sec after brief cessation of walking or jogging.
Miller 1984 (Continued)

**Resistance training included?** No

**Total duration:** 8 weeks or 26 weeks

**Co-interventions:** none described

**Comparator:** usual care (treadmill testing for the first time at 26 weeks)

**Co-interventions:** none described

**Outcomes**

CHD mortality, non-fatal MI and revascularisation

**Source of funding**

Supported by grant from the NHLBI, Bethesda, and by a grant from the PepsiCo Foundation, Purchase, NY

**Conflicts of interest**

Munk 2009

**Study characteristics**

**Methods**

**Study design:** single-centre RCT

**Country:** Norway

**Dates participants recruited:** NR

**Maximum follow-up:** 6 months

**Participants**

**Inclusion criteria:** successful PCI, defined as a residual diameter stenosis after stent implantation of < 20% of the reference diameter

**Exclusion criteria:** history of myocardial infarction (MI) or CABG; significant valvular heart disease; > 80 years; inability to give informed consent; inability to participate in regular training due to residency,
work situation or comorbidity; any known chronic inflammatory disease other than atherosclerosis, or planned surgery within the next 6 months.

**N randomised:** total: 40; intervention: 20; comparator: 20

**Diagnosis (% of participants):**
- Stable angina, post PCI: intervention: 85%; comparator: 95%
- Unstable angina, post PCI: intervention: 15%; comparator: 5%

**Age (mean ± SD):** intervention: 57 ±14; comparator: 61 ± 10

**Percentage male:** Total: 21%; intervention: 18%; comparator: 25%

**Ethnicity:** NR

| Interventions                                                                 | Intervention: starting 11 ± 4 days after PCI, the training model included 10 min warm-up at 60% to 70% of max HR, followed by 4 min intervals at 80% to 90% of max HR, when participants were riding an ergometric bicycle or were running. Intervals were interrupted by 3 minutes of active recovery at 60% to 70% of maximal heart rate. Afterwards, there was a 5-min cool-down, 10 min of abdominal and spine resistance exercises, and 5 min of stretching and relaxing. The training sessions were monitored with individual pulse watches allowing the participant to achieve the target heart rate. |
|                                                                             | Components: exercise only |

Munk 2009 (Continued)

**Blinding of outcome assessment (detection bias)**
- **All outcomes**: Low risk
  - “All scans were analysed twice with EchoPACtm (GE Vingmed Ultrasound) by two blinded investigators. Two experienced cardiologists independently interpreted the images in a blinded manner.” However, not clear if blinded for clinical events and exercise capacity.

**Incomplete outcome data (attrition bias)**
- **All outcomes**: Low risk
  - “No patient was lost to follow up.”

**Selective reporting (reporting bias)**
- **All outcomes**: Low risk
  - All outcomes described in methods were reported at all time points.

Mutwalli 2012

**Study characteristics**

**Methods**
- **Study design**: single-centre RCT
- **Country**: Kingdom of Saudi Arabia
- **Dates participants recruited**: 8 June 2008 to 3 January 2010
- **Maximum follow-up**: 6 months

**Participants**
- **Inclusion criteria**: participants admitted for coronary artery bypass graft (CABG) surgery
- **Exclusion criteria**: history of ejection fraction less than 30%, poor mobility leading to difficulty in walking, chronic atrial fibrillation, repeat CABG or implantable pacemaker were excluded from the study.
- **N randomised**: total: 49; intervention: 28; comparator: 21
- **Diagnosis (% of participants)**: post-CABG: 100%
- **Age (years)**: intervention: 56.75 (range 53.6 to 59.8); comparator: 57.22 (range 54.4 to 60.2)
- **Percentage male**: 100%
- **Ethnicity**: NR

**Interventions**
- **Intervention**: whilst in the cardiac ward, the participants walked daily for 30 minutes. Additionally, before discharge, the participants climbed one flight of stairs and were then asked to walk unaided at a comfortable pace 30 minutes per day until they completed the 6-month home-based CR programme.
- **Components**: exercise plus education
- **Setting**: at home, unsupervised with telephone support
- **Exercise programme modality**: walking
- **Length of session**: 30 minutes
- **Frequency**: daily
- **Intensity**: NR
- **Resistance training included?**: No
- **Total duration**: 6 months
- **Co-interventions**: participants received pre-CABG, immediately post-CABG, and home-based CR program, including education, food management education and a one-hour group workshop which included advice on modifiable and non-modifiable risk factors, change of lifestyle, active life, stress, and then discussed participant’s problems and feelings during the past 2 months. This group workshop was repeated 4 months and 6 months after hospital discharge.
### Mutwalli 2012 (Continued)

**Comparator:** the control group received standard hospital care, including regular advice from doctors and followed usual hospital instructions. This did not include a rehabilitation programme or telephone calls by the study authors.

**Co-interventions:** None described

**Outcomes**
Mortality, MI, hospitalisation and HRQoL

**Source of funding**
"Work was not supported or funded by any drug company."

### Oerkild 2012

**Study characteristics**

**Methods**

- **Study design:** single-centre RCT
- **Country:** Denmark
- **Dates participants recruited:** January 2007 to July 2008
- **Maximum follow-up:** 12 months; mortality data after 5.5 years (mean follow-up 4½ years)

**Participants**

- **Inclusion criteria:** participants ≥ 65 years with a recent coronary event defined as acute myocardial infarction (MI), percutaneous transluminal coronary intervention (PCI) or coronary artery bypass graft (CABG) and who declined participation in centre-based CR
- **Exclusion criteria:** mental disorders (dementia), social disorders (severe alcoholism and drug abuse), living in a nursing home, language barriers or use of wheelchair
- **N randomised:** total: 40; intervention: 19; comparator: 21
- **Diagnosis (% of participants):**
Interventions

Intervention: individualised exercise programmes followed the international recommendations with 30 min exercise/day including 5- to 10-min warm-up (e.g. slow walking) and 10-min cool-down at a frequency of 6 days/week at an intensity of 11 to 13 on the Borg scale. For very disabled participants, the exercise programmes were of shorter duration but then repeated several times a day. At 4 and 5 months, a telephone call was made by the cardiologist to encourage continuous exercising and to answer any medical questions.

Components: exercise plus risk factor management

Setting: unsupervised individualised programme at home, with telephone support

Exercise programme modality: individualised
Length of session: 30 min
Frequency: 6 days a week
Intensity: 11 to 13 on the Borg scale
Resistance training included? No

Total duration: 12 months

Co-interventions: the participants consulted a cardiologist at baseline and after 3, 6 and 12 months, regarding risk factor intervention and medical adjustment. All participants were offered dietary counselling and, if required, smoking cessation.

Comparator: participants received usual care. They received consultation with a cardiologist, and telephone calls at 4 and 5 months. They were not offered exercise education or dietary counselling.

Co-interventions: participants were offered risk factor intervention and medical adjustment by a cardiologist at baseline and after 3, 6 and 12 months.

Oldridge 1991

Study characteristics

Methods

| Study design: multicentre RCT (6 sites) |
| Country: Canada |
| Dates participants recruited: NR |
| Maximum follow-up: 1 year |

Participants

| Inclusion criteria: diagnosis of AMI and scoring > 5 on the short form of the Beck Depression Inventory or > 43 on the Spielberger State Anxiety Inventory or > 42 on the Spielberger Trait Anxiety Inventory while still in hospital |
| Exclusion criteria: residence > 30 miles from the Health Sciences Centre; inability to exercise due to uncontrolled dysrhythmias, heart failure or unstable angina; neurologic, orthopedic, peripheral vascular or respiratory disease; and inability to complete the quality of life questionnaires due to cognitive or language problems |
| N randomised: total: 201; intervention: 99; comparator: 102 |
| Diagnosis (% of participants): MI: 100% |
| Age (mean ± SD): intervention: 52.9 ± 9.5; comparator: 52.7 ± 9.5 |
| Percentage male: intervention: 88%; comparator: 90% |
| Ethnicity: NR |

Interventions

| Intervention: participants attended 50-min exercise sessions twice a week for 8 consecutive weeks. These sessions were held in a hospital gymnasium under the direct supervision of a cardiologist and qualified exercise specialists. There was a 10-min group warm-up at the beginning of each session; stationary cycle ergometry, treadmill walking and arm ergometry followed for 20 to 30 minutes. A cooldown, involving low-intensity activities, concluded the exercise session. |
| Components: exercise and behavioural counselling |
| Setting: centre |
| Exercise programme modality: stationary cycle ergometry, treadmill walking and arm ergometry |
Oldridge 1991 (Continued)

Length of session: 50 min
Frequency: twice a week
Intensity: initially on 65% of the maximal heart rate
Resistance training included? No

Total duration: 8 weeks

Co-interventions: the cognitive behavioural group intervention, facilitated by group leaders without formal training in counselling, consisted of 8 sessions of 90 minutes complemented by progressive relaxation training at the end of the session. Both participant and spouse were invited to attend the group sessions.

Comparator: conventional care

Co-interventions: none described

Outcomes
Mortality. Health-related quality of life: QOLMI time trade-off. Cost data reported in Oldridge 1993

Source of funding
This work was supported by the National Health Research and Development Programme, Health and Welfare, Canada

Conflicts of interest NR

Notes
Both groups improved over 12 months, with the biggest changes occurring in the first 8 weeks.

Ornish 1990

Study characteristics

Study design: multicentre RCT (2 sites)

Country: USA

Dates participants recruited: NR

Maximum follow-up: 5 years
Participants

Inclusion criteria: age 35 to 75 years, male or female; residence in the greater San Francisco area; one, two, or three vessel CAD (defined as any measurable coronary atherosclerosis in a non-dilated or non-bypassed coronary artery); LVEF > 25%

Exclusion criteria: other life-threatening illnesses; MI during the preceding 6 weeks, history of receiving streptokinase or alteplase; currently receiving lipid-lowering drugs; scheduled to receive CABG

N randomised: total: 48; intervention: 28; comparator: 20

Diagnosis (% of participants): moderate to severe CAD: 100%

Age (mean ±SD): Intervention: 56.1 ± 7.5; Comparator: 59.8 ± 9.1

Percentage male: Intervention: 95%; Comparator: 79%

Ethnicity: NR

Interventions

Intervention: the intervention began with a week-long residential retreat at a hotel to teach the lifestyle intervention to the experimental-group participants. Participants then attended regular group support meetings (4 h twice a week). Participants were individually prescribed exercise levels (typically walking) according to their baseline treadmill test results. Participants were asked to exercise for a minimum of 3 h per week and to spend a minimum of 30 min per session exercising within their target heart rates.

Components: exercise plus psychosocial and diet

Setting: centre

Exercise programme modality: typically walking
Length of session: minimum of 30 min
Frequency: up to 6 times a week
Intensity: heart rate of 50-80%
Resistance training included? No

Total duration: 1 year

Co-interventions: stress management, low fat vegetarian diet, group psychosocial support

Comparator: usual care

Co-interventions: none described

Outcomes

CHD mortality, non-fatal MI, revascularisation

Assessment at baseline and after 1 year and 5 years

Source of funding

National Heart, Lung, and Blood Institute of the National Institutes of Health, the Department of Health Services of the State of California, Gerald D. Hines Interests, Houston Endowment Inc, the Henry J. Kaiser Family Foundation. the John E. Fetzer Institute, Continental Airlines, the Enron Foundation, the Nathan Cummings Foundation, the Pritzker Foundation, the First Boston Corporation, Quaker Oats Co., Texas Commerce Bank, Corrine and David Gould, Pacific Presbyterian Medical Center Foundation, General Growth Companies, Arthur Andersen and Co.

Conflicts of interest

NR

Notes

Intervention group had 91% reduction in reported frequency of angina after 1 year and 72% after 5 years; comparator group had 186% increase in reported frequency of angina after 1 year and 36% decrease after 5 years.

Intervention group had 7.9% relative improvement in coronary artery diameter at 5 years, comparator group had 27.7% relative worsening at 5 years.

### Study characteristics

#### Methods
- **Study design:** single-centre RCT
- **Country:** India
- **Dates participants recruited:** February 2007 to July 2010
- **Maximum follow-up:** 18 months

#### Participants
- **Inclusion criteria:** “Patients with proven CAD were recruited. Disease was diagnosed by history of electrocardiograms, echocardiography and treadmill testing. Their willingness to complete the entire span of the project (18 months) was assured.”
- **Exclusion criteria:** “Patients who had other co-morbid conditions (e.g. malignant hypertension, diabetes mellitus, chronic obstructive pulmonary disease, asthma, diseases of the nervous system, endocrinological disorders, congenital heart disease) and patients with known complications of CAD, those on pacemakers, and those who had undergone bypass surgery were excluded from the study”
- **N randomised:** total: 258; intervention: 129; comparator: 129
- **Diagnosis (% of participants):** participants with proven CAD (100%)
- **Age (mean ±SD):** Intervention: 59.1 ± 9.9; Comparator: 56.4 ± 10.9
- **Percentage male:** intervention: 80%; comparator: 81%
- **Ethnicity:** NR

#### Interventions
- **Intervention:** yogic intervention plus medication performed in the Department of Physiology at Chhatrapati Sahuji Maharaj Medical University under the guidance and supervision of yoga experts. 35 to 40 minutes per day, for 5 days per week over 18 months.
- **Components:** exercise only
- **Setting:** centre
- **Exercise programme modality:** yoga

Participants

**Inclusion criteria**: male with coronary artery disease, planned myocardial revascularisation surgery (cardiopulmonary bypass)

**Exclusion criteria**: age over 65 years, unstable angina pectoris, recent MI (less than 30 days), changes in ECG making it difficult to interpret the QRS complex and ST segment, atrial fibrillation and other serious cardiac arrhythmias, decreased LVEF (< 40%), pulmonary hypertension, respiratory and renal failure, metabolic (obesity, decompensated diabetes mellitus) and concomitant diseases that prevent exercise

**N randomised**: total: 114; intervention 1 (cycling): 36; intervention 2 (walking): 36; comparator: 42

**Diagnosis (% of participants)**: CABG (100%)

**Age (median, IQR)**: intervention 1 (cycling): 57, 51-59; intervention: 56, 51-57; comparator: 56 (51-57)

**Percentage male**: 100%

**Ethnicity (white %)**: NR

Interventions

**Intervention**:  
- Group 1: controlled aerobic exercise carried out on a stationary bike  
- Group 2: independent dosed walking at home, with training pace controlled by pedometer

**Components**: Exercise only

**Setting**: group 1 - hospital-based; group 2 - home-based

**Exercise programme modality**: group 1 - cycling; group 2 - walking

**Length of session**: 30 minutes

**Frequency**: group 1: 3 sessions per week; group 2: at least 3 times per week

**Intensity**: group 1: 50% to 75% peak heart rate; group 2: walking pace determined by calculation using cycle ergometry test, target heart rate 50% to 75% peak

**Resistance training included**: No

**Total duration**: 3 months

**Co-interventions**: None described

**Comparator**: Medication plus monthly telephone follow-up

**Co-interventions**: None described

Outcomes

HRQoL (results not reported)

Source of funding

Prabhakaran 2020

**Study characteristics**

**Methods**  
**Study design:** multicentre RCT (24 sites)  
**Country:** India  
**Dates participants recruited:** August 2014 - March 2018  
**Maximum follow-up:** median follow-up 21.6 months

**Participants**  
**Inclusion criteria:** participants aged 18 to 80 years with acute myocardial infarction within the past 14 days were eligible if they were willing and able to complete the hospital-based CR programme. Acute MI confirmed by the WHO definition (presence of symptoms of ischaemia and changes in ECG) or the Third Universal definition of MI (elevation of a cardiac biomarker along with the presence of other symptoms of MI or changes in ECG).
Exclusion criteria: participants who practised yoga regularly (i.e. > 3hr per week) or were participating in other clinical trials. Those with diseases that limited their life span to < 1 year or considered unlikely to complete the study by the local investigator.

Diagnosis (% of participants): MI: 100%

Age (mean ± SD): intervention: 53.4 ± 11; comparator: 53.4 ± 10.8

Percentage male: intervention: 86.2%; comparator: 85.9%

Ethnicity: NR

Interventions

Intervention: Yoga-care program. 13 direct contact sessions over 12 weeks. First two sessions delivered individually and the remainder in groups at the hospital. Group sessions lasted ~75 minutes and involved a combination of exercises related to general physical conditioning, stress and relaxation (health rejuvenating exercises - around 10 min, yoga poses - 25 min, breathing exercises - 15 min, meditation and relaxation practices - 15 min; and moderated discussion - 10 min), and some exercises believed to be of particular cardio-protective benefit in yogic texts. The lifestyle and other educational components were informed by yogic ideas but moderated by established scientific evidence. Sessions led by yoga teachers trained in delivery of yoga-care program. Participants were also encouraged to practice daily at home following the instructions provided in a DVD and booklet.

Components: exercise and education

Setting: centre-based

Exercise programme modality: yoga

Length of session: 75 min

Frequency: at least once a week

Intensity: not reported

Resistance training included? No

Total duration: 12 weeks

Co-interventions: None described

Comparator: Enhanced standard care in the form of educational advice leaflets (once before discharge, at 5 and 12 weeks) along with standard medical care as elsewhere in India but does not include rehabilitation.

Co-interventions: none described

Outcomes

Mortality, MI, hospitalisations, HRQoL (only at 12 weeks), cost effectiveness

Source of funding

Indian Council of Medical Research and the Medical Research Council, United Kingdom

Conflicts of interest

Dr. Chathurvedi has served as a member of the Data Safety and Monitoring Committee for AstraZeneca. All other authors have reported that they have no relationships relevant to the contents of this paper to disclose.

### Reid 2012

**Study characteristics**

**Methods**

- **Study design:** multicentre RCT (2 sites)
- **Country:** Canada
- **Dates participants recruited:** December 2004 to December 2007
- **Maximum follow-up:** 12 months

**Participants**

- **Inclusion criteria:** Admitted for acute coronary syndromes who: underwent successful percutaneous coronary revascularisation; were not planning on enrolling in CR; had Internet access at home or work; and were 20 to 80 years of age.
- **Exclusion criteria:** CABG; implantable cardioverter-defibrillator; NYHA Class III or IV heart failure; inability to speak and read English.
- **N randomised:** total: 223; intervention: 115; comparator: 108
- **Diagnosis (% of participants):**
  - AMI this admission: 29.1%
  - PCI this admission: 98.2%
  - First cardiac event: 64.6%
  - Previous AMI: 18.8%
  - Previous PCI: 27.4%
  - Previous CABG: 9.0%
- **Age (mean ± SD):** intervention: 56.7 ± 9.0; comparator: 56.0 ± 9.0
- **Percentage male:** intervention: 82.6%; comparator: 86.1%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** Participants were visited in hospital by an exercise specialist, who presented a personally tailored physical activity plan and instructions on how to access the CardioFit website. Following discharge, participants were asked to log their daily activity on the CardioFit website and complete a series of five online tutorials (at weeks 2, 4, 8, 14, and 20). Following each tutorial, a new physical activity plan was developed. Between tutorials, participants received emails from the exercise specialist providing motivational feedback on their progress.
Reid 2012 (Continued)

Components: exercise plus psychological support

Setting: home

Exercise programme modality: NR
Length of session: NR
Frequency: NR
Intensity: NR
Resistance training included? NR

Total duration: 20 weeks

Co-interventions: the CardioFit website and tutorials were designed to foster behavioural capability, self-efficacy, social support, and realistic outcome expectations. Tutorials were organised to engage self-control processes including exercise planning, goal setting, monitoring and self-regulation, and relapse prevention.

Comparator: physical activity guidance from their attending cardiologist and an education booklet.

Co-interventions: none described

Outcomes HRQoL

Source of funding Heart and Stroke Foundation of Ontario. Dr Reid was supported by a New Investigator Award from the Heart and Stroke Foundation of Canada. Dr Blanchard is supported by the Canada Research Chairs programme.

Conflicts of interest "The authors declare that there is no conflict of interests"

Notes

Risk of bias

Bias Authors’ judgement Support for judgement

Random sequence generation (selection bias) Low risk "Participants were randomized ... using a random sequence that was computer generated by a statistical consultant in blocks of 4, 8, and 10."

Allocation concealment (selection bias) Low risk "Sequences were generated for Ottawa and London and placed in sealed, numbered envelopes to ensure that treatment allocation was concealed until after baseline data collection. Research coordinators allocated the next available number on study entry (while the participant was still hospitalized)"

Blinding of outcome assessment (detection bias) Low risk "Research assistants, blinded to the participants’ treatment allocation, conducted follow-up assessments"

Incomplete outcome data (attrition bias) All outcomes High risk Loss to follow-up was well reported but was high in both groups 36/115 [31%] and 33/108 [31%] were lost to follow-up from the intervention and control groups.

Selective reporting (reporting bias) Low risk All outcomes described in the methods section are reported in results.

Roman 1983

Study characteristics
Methods

Study design: single-centre RCT
Country: Chile
Dates participants recruited: June 1973 to June 1981
Maximum follow-up: 9 years

Participants

Inclusion criteria: participants with transmural AMI
Exclusion criteria: severe arrhythmias persisting after the acute phase of AMI (frequent ventricular premature beats, grade iii-iv of the Lown classification, atrial flutter, partial or complete AV block); great left-ventricular enlargement; left ventricular aneurysm; persistent cardiac failure; severe diastolic hypertension post-myocardial infarction angina.

N randomised: total: 193; intervention: 93; comparator: 100

Diagnosis (% of participants):
- Transmural AMI: 100%
- Anterior wall infarction: 55%
- Posteroinferior infarction: 45%

Age (mean ± SD):
- intervention: 56.2 ± 10.3
- comparator: 59.1 ± 8.8

Percentage male:
- intervention: 93.6%
- comparator: 87%

Ethnicity: NR

Interventions

Intervention: Supervised physical training programme according to the guidelines reported by Zohman and Tobias. It was started with combined ergometric, callisthenic and walk-jogging exercise lasting 30 min, three times a week. The intensity of the training was graded according to the target heart rate threshold, defined as 70% of maximal heart rate achieved by the participant in the former ergometric work test.

Components: exercise only
Setting: centre
Exercise programme modality: combined ergometric and walk-jogging exercise
Length of session: 30 min
Frequency: three times a week
Intensity: 70% of maximal heart rate
Resistance training included? Callisthenics
Total duration: average 42 months (range 6 to 108 months)

Co-interventions: none described
Comparator: Control participants were medically treated according to the guidelines commonly used; namely, short- and long-lasting nitrites, β- blockers or Ca antagonists (nifedipine).

Co-interventions: A small number (8 participants) were also treated with oral anticoagulants.

Outcomes

Mortality, MI and revascularisations

Source of funding
NR

Conflicts of interest
NR

### Sandström 2005

#### Study characteristics

**Methods**

- **Study design:** single-centre RCT
- **Country:** Sweden
- **Dates participants recruited:** NR (recruited over a period of 2½ years)
- **Maximum follow-up:** 12 months

**Participants**

- **Inclusion criteria:** participants > 65 years admitted following an acute coronary event. Participants had to perform a pre-discharge exercise test with a workload of ≥ 70 watts in men and ≥ 50 watts in women.
- **Exclusion criteria:** participants with neurological sequelae, memory dysfunction such as dementia, orthopaedic disability, inability to speak or understand Swedish, or both, and a planned coronary intervention within 3 months.
- **N randomised:** total: 101; intervention: 50; comparator: 51
- **Diagnosis (% of participants):**
  - Angina pectoris: intervention: 20%; comparator: 21%
  - Previous AMI: intervention: 18%; comparator: 11%
  - Acute coronary event: intervention: 50%; comparator: 51%
  - Previous PCI: intervention: 7%; comparator: 5%
  - Previous CABG: intervention: 9%; comparator: 9%
  (Not mutually exclusive numbers.)
- **Age (median):** total: 71 years (range 64-84); intervention: 71 years (range 64-84); comparator: 71 years (range 65-83)
Cochrane Data Base of Systematic Reviews

Sandström 2005 (Continued)

**Percentage male:** total 80.2%; intervention: 82%; comparator: 78.4%

**Ethnicity:** NR

**Interventions**

**Intervention:** 50 min aerobic group training programme three times a week for 3 months, with a voluntary 50 min step-down period once a week for another 3 months. The complete programme was supported by music, which guided the intensity of the performance during the session. The training sessions were followed by 10 min of relaxation, also supported by music.

**Components:** exercise only

**Setting:** centre-based supervised group sessions

**Exercise programme modality:** aerobic exercises to music

**Length of session:** 50 min with a voluntary 50 min step-down period once a week for another 3 months

**Frequency:** 3 times a week

**Intensity:** NR

**Resistance training included?** No

**Total duration:** 3 months

**Co-interventions:** none described

**Comparator:** participants were recommended to take a daily walk at a comfortable speed, and to gradually increase the time, length and speed, and were encouraged to restart their prior physical activity as soon as they felt fit enough for this.

**Co-interventions:** none described

**Study characteristics**

### Methods

- **Study design:** single-centre RCT
- **Country:** Spain
- **Dates participants recruited:** June 2010 - June 2012
- **Maximum follow-up:** 12 months

### Participants

- **Inclusion criteria:** Age over 18 years, diagnosis of myocardial ischaemia (MI pre-infarct angina, angina pectoris, other specific forms of chronic ischaemic heart disease or unspecified ischaemic heart disease) during the current admission, residence in the catchment area of the hospital, absence of cognitive deficit (Pfeiffer test: 0-2 mistakes), sufficient functional capacity to follow the CRP (Barthel index > 60), and willingness to participate in the study and provide signed informed consent.

- **Exclusion criteria:** Symptoms of right heart failure producing pulmonary hypertension or dyspnoea caused by severe pulmonary pathology, additional comorbidities affecting the prognosis of cardiac disease, major comorbidities or limitations that could interfere with the exercise training programme.

- **N randomised:** total: 86; intervention: 42; comparator: 44

- **Diagnosis (% of participants):** intervention: myocardial ischaemia (85.4%), pre-infarct angina (4.9%), cardiac angina (9.8%); comparator: myocardial ischaemia (72.7%), pre-infarct angina (13.6%), cardiac angina (11.4%), other specific forms of chronic ischaemic heart disease (2.3%).

- **Age (mean ± SD):** intervention: 59.4 ± 12; comparator: 59.7 ± 10.4

- **Percentage male:** intervention: 93%; comparator: 77%

- **Ethnicity:** NR

### Interventions

- **Intervention:** Supervised outpatient exercise training programme based on the results of the exercise stress test and mindful of comorbid conditions and physical limitations. Intervention started within 3 days of exercise test which was performed within 1 month of discharge. Hospital-based programme of physiotherapist-supervised exercise (3 hours/week spread over 3 days), for 10 weeks. Classes consisted of 10 minutes of warm-up and muscle stretching, 30 minutes of aerobic exercises on a cycle ergometer, 15 minutes of isotonic exercises for the upper and lower limbs and 5 minutes of cool-down. Aerobic exercise intensity was between 75% and 90% of the maximum heart rate obtained in the previous exercise stress test and progressed according to the perceived exertion rate score of 11–15. Resistance training was performed with 10–15 repetitions for three sets, maintaining a perceived exertion rate score of 11–14.

- **Components:** exercise only

- **Setting:** centre-based

- **Exercise programme modality:** cycle ergometry

- **Length of session:** 1 hour

- **Frequency:** 3 sessions per week

- **Intensity:** 75-90% peak heart rate, RPE 11-15

- **Resistance training included?** Yes – upper and lower limb isotonic exercises, 10-15 repetitions, 3 sets, RPE 11-14

- **Total duration:** 10 weeks

- **Co-interventions:** None described

- **Comparator:** Standard care, given oral and written information about cardiovascular risk factors during hospitalisation. Participants instructed to do exercises to regain mobility and maintain muscle tone and peripheral circulation and taught breathing exercises. Participants provided guidance on how to return to physical activity. Scheduled for follow-up visits at 3, 6 and 12 months post discharge to control risk factors, reinforce education measures and review adherence to cardiac medication.
Santaularia 2017 (Continued)

**Co-interventions:** none described

**Outcomes**
Mortality, hospitalisations, HRQoL

**Source of funding**
Supported by a grant from the Col·legi de Fisioterapeutes de Catalunya (no.: R01/08-09)

### Schuler 1992

#### Study characteristics

**Methods**

**Study design:** single-centre RCT. Participants randomised after routine angiography for angina.

**Country:** Germany

**Dates participants recruited:** NR

**Maximum follow-up:** 6 years

**Participants**

**Inclusion criteria:** Male, stable symptoms, willingness to participate in the study for at least 12 months, coronary artery stenoses well documented by angiography, and permanent residence within 25 km of the training facilities at Heidelberg.

**Exclusion criteria:** Unstable angina pectoris, left main coronary artery stenosis > 25% luminal diameter reduction, severely depressed left ventricular function (ejection fraction < 35%), significant valvular heart disease, insulin-dependent diabetes mellitus, primary hypercholesterolaemia (type II hyperlipoproteinaemia, low density lipoprotein [LDL] > 210 mg/dL), and occupational, orthopedic, and other conditions precluding regular participation in exercise sessions.

**N randomised:** total: 113; intervention: 56; comparator: 57

**Diagnosis (% of participants):** AMI: 66%

**Age (mean ± SD):** intervention: 52.8 ± 5.8; comparator: 54.2 ± 7.7
Interventions

**Intervention:** participants stayed on a metabolic ward during the initial 3 weeks, during which they were instructed how to lower the fat content of their regular diet. Participants were asked to exercise daily at home on a cycle ergometer for a minimum of 30 minutes close to their target heart rates, which were determined as 75% of the maximal heart rate during symptom-limited exercise. In addition, they were expected to participate in at least two group training sessions of 60 minutes each week.

**Components:** exercise and education.

**Setting:** centre (group session) and unsupervised at home.

**Exercise programme modality:** cycle ergometer.

**Length of session:** 30 min at home and 60 min group session.

**Frequency:** daily at home; twice a week at centre.

**Intensity:** 75% maximal HR.

**Resistance training included?** No.

**Total duration:** 12 months.

**Co-interventions:** participants were on their regular antianginal medication, including β-blocking agents.

**Comparator:** participants spent 1 week on the metabolic ward, where they received identical instructions about the necessity of regular physical exercise and how to lower fat consumption. "Usual care" was rendered by their private physicians.

**Co-interventions:** They were asked not to take lipid-lowering medications.

**Outcomes**

Total and CHD mortality, non-fatal MI, revascularisation.

**Source of funding**

Bundesministerium für Forschung und Technologie, Bonn, FRG.

**Conflicts of interest**

NR

**Notes**

Exercise adherence in the first year was 68% (39% to 92%), over the next 5 years 33% (3% to 89%). Participants with regression of coronary atheroma attended exercise sessions significantly more often (54 +/- 24%) than participants with no change (20 +/- 24%) or progression (31 +/- 20%).

<tr>
<td><strong>Intervention:</strong></td>
<td>participants participated in an outpatient phase III CR program for 6 months. The weekly supervised exercise session at the clinic consisted of approximately 20 min of warm-up exercises including stretching and callisthenics, followed by 20–30 min of continuous upright aerobic and dynamic exercise (various combinations of walking, bicycling, jogging, and other activities) and light isometric exercise, such as hand weights, and approximately 20 min of cool-down stretching and callisthenics. The intensity of exercise was prescribed individually at the anaerobic threshold level measured by a symptom-limited treadmill exercise test at baseline. In addition to the supervised exercise session, participants were encouraged to exercise twice a week outside of the clinic. Each participant’s exercise prescription was also periodically adjusted on the basis of repeated treadmill exercise test to encourage a gradual increase in overall exercise performance.</td>

Seki 2008

Study characteristics

Methods

Study design: single-centre RCT

Country: Japan

Dates participants recruited: NR

Maximum follow-up: 6 months

Participants

Inclusion criteria: > 65 years old with stable CAD

Exclusion criteria: Ongoing congestive heart failure, liver dysfunction, renal dysfunction, or systemic diseases, including malignancy and collagen disease.

N randomised: total: 39; intervention: 20; comparator: 19

Diagnosis (% of participants):
stable CAD: 100%
MI: 46%
PCI: 31%
CABG: 36%

Age (mean ± SD): intervention: 69±3; comparator: 70±4
Percentage male: 100%
Ethnicity: NR

Interventions

**Intervention:** Weekly outpatient phase III cardiac rehabilitation programme that included an exercise session, exercise prescription, dietary instruction and an educational programme for 6 months. Supervised exercise sessions at the clinic consisted of approximately 15 min of warm-up exercises including stretching, followed by 20 to 60 min of continuous upright aerobic exercise and light isotonic exercise such as sit-ups and squatting using the participant’s own body weight, followed by approximately 15 min of cool-down stretching and callisthenics. The intensity of exercise was prescribed individually at the anaerobic threshold (AT) level as measured by a treadmill exercise test using expiratory gas analysis or a rating of 12 to 13 on the standard Borg perceived exertion scale. In addition to the weekly supervised exercise sessions, participants were encouraged to perform aerobic exercise twice weekly (≥ 30 min) at home at an intensity of heart rate of AT or a rating of 12 to 13 on the Borg scale.

**Components:** exercise and education.

**Setting:** Centre and home.

**Exercise programme modality:** e.g. walking, bicycling, jogging.

**Length of session:** 50 to 110 min at the centre; ≥ 30 min at home.

**Frequency:** weekly at the centre plus twice a week at home.

**Intensity:** 12 to 13 on the standard Borg scale.

**Resistance training included?** Callisthenics.

**Total duration:** 6 months.

**Co-interventions:** participants were instructed about the phase II diet of the American Heart Association at the beginning and every 2 months of the study. An educational programme was also given to each subject by physicians and nurses regarding ischaemic heart disease and risk factors at baseline. Subjects were frequently encouraged by physicians, dietician, nurses, and exercise physiologists to comply with both exercise and dietary instructions throughout the programme. Standard medical care was provided for both groups. Lipid-lowering drugs and other medications that may affect lipid levels were given at stable doses for at least 4 weeks before entry, and the doses of these medications were not altered during the study period.

**Comparator:** usual outpatient care.

**Co-interventions:** none described.

Outcomes

**Total mortality; non-fatal/fatal mortality.**

Source of funding

Conflicts of interest

NR

**Notes**

“No subject in either group showed any worsening of symptoms or had clinical events during this study.”

### Study characteristics

#### Methods

- **Study design:** Multicentre RCT (5 sites)
- **Country:** USA
- **Dates participants recruited:** 1976
- **Maximum follow-up:** 5 years

Participants were randomised after completion of a 6-week, low-level exercise programme run-in period.

#### Participants

- **Inclusion criteria:** documented MI ≥ 8 weeks but ≤ 3 years before being enrolled. Other eligibility criteria included the ability to exercise at an intensity level ≥ 3 metabolic equivalents (METs) and a supine resting diastolic blood pressure < 100 mmHg.

- **Exclusion criteria:** participants were considered ineligible if they had any other significant coexisting CVD or other disease likely to be fatal in the near future, uncontrolled diabetes mellitus, complete heart block with or without ventricular pacemaker, or emotional or physical impairments that would make participation and adherence difficult, or if they were already participants in a formal exercise programme.

- **N randomised:** total: 651; intervention: 323; comparator: 328
- **Diagnosis (% of participants):** MI: 100%
- **Age (mean ± SD):** intervention: 51.5 ± 7.4; comparator: 52.1 ± 7.2
- **Percentage male:** 100%
- **Ethnicity % white:** intervention: 93.3%; comparator: 94.4%

#### Interventions

- **Intervention:** An exercise prescription was developed on the basis of each participant’s multistage graded exercise test (MSET) results. An exercise target heart rate guided the prescription and was determined as 85% of the peak heart rate achieved on the test. This group performed brisk physical activity in the laboratory for 8 weeks, exercising 1 hour per day, 3 days per week. The participants were supervised and underwent continuous ECG monitoring. Each individual exercised for 4 minutes on each of 6 stationary machines with a 2-minute rest interval between machines. Attainment of the target heart rate was the goal for every 4-minute exercise period.
After 8 weeks, participants exercised in a gymnasium or swimming pool without ECG monitoring, although exercise heart rates were periodically checked. Activities consisted of 15 minutes of continuous jogging, cycling, or swimming, followed by 25 minutes of recreational games. The activities were performed at an intensity level enabling each participant to reach his individually prescribed target heart rate. The men were encouraged to attend 3 sessions per week but in some situations were allowed to exercise on their own.

Components: exercise only.

Setting: group sessions in centre ("but in some situations were allowed to exercise on their own").

Exercise programme modality: "brisk physical activity" on “stationary machines”.

Length of session: 40 min.

Frequency: 3 days per week.

Intensity: 85% of the peak heart rate.

Resistance training included? No

Total duration: 8 weeks in the laboratory, followed by regular jogging, cycling, or swimming and recreational games.

Co-interventions: none described.

Comparator: Participants in the non-exercising control group were encouraged to maintain normal routines but not to participate in any regular exercise programme.

Co-interventions: none described.

</tbody>
</table>

Notes
90% of ET attended 90% of 24 scheduled sessions post-randomisation, only 48% attending > 50% of sessions at 18 months.
30% of control alleged exercising regularly, on own initiative.
At 19 years any protective effect from the programme had decreased over time, but an increase with PWC from the beginning to the end of the trial was associated with a consistent reduction in mortality throughout the 19 years of follow-up.

**Study characteristics**

### Methods
- **Study design:** Multicentre RCT (7 sites)
- **Country:** USA
- **Dates participants recruited:** 1 September 1977 to 2 December 1979
- **Maximum follow-up:** 6 months

Random allocation of individuals to two intervention groups (exercise only (Intervention B1) or exercise plus teaching and counselling (Intervention B2)) and a control group (usual care).

### Participants
- **Inclusion criteria:** Previous MI, age < 70 years, living < 50 miles of centre.
- **Exclusion criteria:** prolonged complications, physical limitations, noncardiac or cardiac diseases, communication problems, other issues e.g. massive obesity, psychological problems, etc.
- **N randomised:** total: 258; Intervention B1: 88; Intervention B2: 86; comparator: 84
- **Diagnosis (% of participants):** AMI: 100%
- **Age (mean ±SD):** Intervention B1: 55.6 ± 9.3; Intervention B2: 56.3 ± 8.3; comparator = 57.1 +/- 7.3
- **Percentage male:** > 80%
- **Ethnicity:** > 80% white

### Interventions
- **Intervention:** The outpatient exercise programme was identical for the participants in groups B1 and B2. It consisted of a gradually progressive callisthenic and walking programme prescribed at weekly 30-minute clinic visits and performed by the participant at home. Participants were instructed to exercise twice a day until they returned to work and once a day thereafter. If the participant was symptom free, the prescription was gradually increased to add callisthenics of increasing intensity and the distance and time (or rate) of walking were gradually advanced.
- **Components:** exercise only or exercise plus education and counselling.
- **Setting:** centre and home.
- **Exercise programme modality:** walking.
- **Length of session:** NR
- **Frequency:** twice a day until return to work and once a day thereafter.
- **Intensity:** NR
- **Resistance training included?** callisthenics.
- **Total duration:** NR

**Co-interventions:** participants in group B2, in addition to receiving exercise prescriptions as described above, attended a series of eight 1-hour group sessions during weekly clinic visits. The sessions emphasised the practical aspects of anatomy and physiology of the heart, coronary artery disease, myocardial infarction and medications; risk factors, including smoking, hypercholesterolaemia, hypertension, stress and sedentary living; nutritional aspects of fats, cholesterol, salt and alcohol; activities and exercises; emotional reactions to myocardial infarction in participants and their families; resumption of sexual activity; and issues concerning return to work or, if retired, to an alternative, meaningful lifestyle.

**Comparator:** conventional medical and nursing management throughout all phases of hospitalisation and convalescence at home.

**Co-interventions:** none described.

Snoek 2020

Study characteristics

Methods

- **Study design:** Multicentre RCT (6 sites across 5 countries)
- **Country:** Europe (the Netherlands, Denmark, Spain, Switzerland, France)
- **Dates participants recruited:** November 2015 - January 2018
- **Maximum follow-up:** 12 months

Participants

- **Inclusion criteria:**
  - Participants of 65 years or older who are a candidate for CR and non-voluntary to participate in the regular CR programme
  - Signed written informed consent
  - One of the following criteria:
    - participants with an acute coronary syndrome, including myocardial infarction (MI) and/or revascularisation within 3 months prior to the start of the CR program
    - participants that underwent a percutaneous coronary intervention (PCI) within 3 months prior to the start of the CR programme
participants that received coronary artery bypass grafting (CABG) within 3 months prior to the start of the CR programme

- participants who were treated surgically or percutaneously for valvular heart disease (including TAVI) within 3 months prior to the start of the CR programme

- participants with a stable angina with documented significant CAD (defined by standard non-invasive or invasive methods)

**Exclusion criteria:**

- Contraindication to CR
- Mental impairment leading to inability to cooperate
- Severe impaired ability to exercise
- Signs of severe cardiac ischaemia and/or a positive exercise testing on severe cardiac ischaemia
- Insufficient knowledge of the native language
- No access, availability or insufficient knowledge of a computer with internet
- Implanted cardiac device (pacemaker, ICD)

**N randomised:** total: 179; intervention: 89; comparator: 90.

**Diagnosis (% of participants):**

- PCI: intervention 63 (71%); control 65 (72%)
- CABG: intervention 11 (12%); control 8 (9%)
- Valve replacement: intervention 1 (1%); control 3 (3%)
- None: intervention 14 (16%); control 14 (16%)

**Age (mean ± SD):** intervention: 72.4 ± 5.4; comparator 73.6 ± 5.5

**Percentage male:** intervention: 78%, comparator: 84%

**Ethnicity:** intervention: 99%, comparator: 99% white

**Interventions**

**Intervention:** 6-month home-based CR program equipped with a smartphone and heart rate belt. Participants instructed to exercise at moderate intensity for at least 30 minutes per day, 5 days per week. Motivational interviewing was applied by telephone weekly in the first month, every other week in the second month, and monthly until completion of the program at 6 months.

**Setting:** Home-based

**Exercise programme modality:** Self-chosen type of activity

**Length of session:** > 30 minutes

**Frequency:** five sessions per week.

**Intensity:** self-selected level of intensity (guided by RPE and heart rate zones)

**Resistance training included?** NR

**Total duration:** 6 months.

**Co-interventions:** none described

**Comparator:** participants in the control group did not receive any form of cardiac rehabilitation but received locally defined standard of care.

**Co-interventions:** none described.

**Outcomes**

Mortality, MI, PCI, cardiovascular hospitalisation, HRQoL

**Source of funding**

Study was supported by grant 634439 from the European Union’s Horizon 2020 Research and Innovation Programme and contract 15.0139 from the Swiss State Secretariat for Education, Research and Innovation.
Mr Snoek reported receiving grants from European Union’s Horizon 2020 Research and Innovation Programme during the conduct of the study. Dr van der Velde reported receiving grants from the European Union during the conduct of the study. Dr Eijsvogels reported receiving a personal grant from the Dutch Heart Foundation. Dr Prins reported receiving grants from the European Commission during the conduct of the study and outside the submitted work. Dr Bruins reported receiving grants from Isala Heart Centre during the conduct of the study. Dr Meindersma reported receiving grants from the European Commission during the conduct of the study. Dr González-Salvado reported receiving grants from the European Union during the conduct of the study. Dr Iliou reported receiving personal fees and non-financial support from Servier Laboratories, non-financial support from Novartis International AG and Sanofi SA, and personal fees from AstraZeneca outside the submitted work. Dr Marcin reported receiving grants from the Swiss National Fond during the conduct of the study. Dr Van’t Hof reported receiving grants from the European Union during the conduct of the study and grants from Medtronic plc, AstraZeneca, and Abbott Laboratories outside the submitted work. Dr de Kluiver reported receiving grants from the European Union during the conduct of the study and having an indirect interest in HC@home/Mobilhealth, which provided the hardware and software for this study, outside the submitted work. No other disclosures were reported.

**Specchia 1996**

**Study characteristics**

**Methods**

- **Study design:** single-centre RCT
- **Country:** Italy
- **Dates participants recruited:** NR (40-month period)
- **Maximum follow-up:** mean 34.5 months
Specchia 1996  (Continued)

Participants

**Inclusion criteria:** participants < 65 years of age who had not had previous MI, admitted due to chest pain lasting > 30 minutes and because they had a diagnosis of AMI based on evolutionary ECG changes and serum kinase elevation.

**Exclusion criteria:** complicated in-hospital clinical course e.g. post-infarction angina requiring urgent revascularisation; evidence of congestive HF; chronic concomitant illnesses or musculoskeletal handicaps that would prevent them from finishing the exercise training period.

**N randomised:** total: 256; intervention: 125; comparator: 131

**Diagnosis (% of participants):**

MI: 100%

Prior angina: 42%

**Age (Mean ± SD):** intervention: 51.5 ± 7; comparator: 54.3 ± 8

**Percentage male:** intervention: 91%; comparator: 91%

**Ethnicity:** NR

Interventions

**Intervention:** participants underwent a 4-week physical training period consisting of supervised training sessions of 30 minutes of bicycle ergometry five times a week combined with callisthenics. Training intensity was graded according to 75% of maximal work capacity reached in the previous exercise test. At the end of the 4-week training period, a second symptom-limited exercise test was performed. Participants were then discharged with the instructions to continue the callisthenics daily and to walk for ≥ 30 minutes every 2 days.

**Components:** exercise, education and psychology.

**Setting:** centre and then home.

**Exercise programme modality:** bicycle ergometry in centre followed by callisthenics and walking at home.

**Length of session:** ≥ 30 minutes.

**Frequency:** five times a week in centre followed by daily callisthenics and walking every other day.

**Intensity:** 75% of maximal work capacity.

**Resistance training included?** Callisthenics.

**Total duration:** 4 weeks supervised and then continued at home.

**Co-interventions:** All participants went to the Rehabilitation Center for 3 weeks and underwent a symptom-limited exercise test (28 ± 2 days after myocardial infarction), 24-hour Holter monitoring, and coronary arteriography (31 ± 3 days after the acute episode). All participants attended colloquial sessions, held by a cardiologist and a psychologist, dealing with secondary prevention of cardiovascular diseases and stressing dietary changes and smoking cessation.

**Comparator:** Discharged after rehab centre and clinically re-examined 1 month later when they underwent a second symptom-limited exercise test.

**Co-interventions:** as above

Outcomes

CHD mortality, revascularisations

Source of funding

NR

Conflicts of interest

NR

Notes

Ejection fraction (EF) was the only prognostic factor. Among 51 participants with EF < 41%, relative risk for the 27 untrained participants was 8.63 times higher than for 24 trained ones. (P = 0.04)
If EF > 40%, estimated risk for untrained participant was 1.07 times higher than for trained.

Ståhle 1999

Study characteristics

Methods

**Study design:** single-centre RCT

**Country:** Sweden

**Dates participants recruited:** October 1994 to June 1997

**Maximum follow-up:** 1 year

Participants

**Inclusion criteria:** participants ≥ 65 years admitted because of an acute coronary event. To be included, the participants had to perform a pre-discharge exercise test at a workload ≥ 70 W in men and ≥ 50 W in women. For the group with unstable angina pectoris, a ST60 depression of > 1 mm in ≥ two adjacent leads had to be documented at the exercise test.

**Exclusion criteria:** neurological sequelae, memory dysfunction, orthopaedic disability, inability to understand Swedish, coronary intervention planned within 3 months or other complicating diseases.

**N randomised:** total: 109; intervention: 56; comparator: 53

**Diagnosis (% of participants):**

Congestive heart failure: 6%

Previous AMI: 27%
Angina pectoris: 38%
Previous PCI: 11%
Previous CABG: 17%

**Age years, (range):** intervention: 71 (64-84); comparator: 68 (65-83)

**Percentage male:** intervention: 73%; comparator: 75%
**Interventions**

**Intervention:** 50 min aerobic outpatient group-training programme (including warm-up and cool-down) 3 times a week for 3 months. Complete programme was supervised by specialised physiotherapist and supported by music which guided intensity of performance during session. Training followed by 10 min of music-supported relaxation. After 3 months, participants had possibility of participating in programme once a week for another 3 months.

**Components:** exercise.

**Setting:** supervised centre-based group sessions.

**Exercise programme modality:** NR

**Length of session:** 50 min plus 10 min relaxation.

**Frequency:** 3 times a week.

**Intensity:** NR

**Resistance training included?** NR

**Total duration:** 3 months followed by opportunity to continue once a week for another 3 months.

**Co-interventions:** none described

**Comparator:** usual care - encouraged to re-start usual/prior physical activity as soon as they felt fit.

**Co-interventions:** none described

**Outcomes**

Total mortality, CABG, PCI, health-related quality of life; Karolinska Questionnaire at 12-months.

### Study characteristics

#### Methods

**Study design:** single-centre RCT  
**Country:** USA  
**Dates participants recruited:** NR  
**Maximum follow-up:** 1 year.  
Randomised by blocks of 6 into one of three groups: exercise, group counselling & control.

#### Participants

**Inclusion criteria:** Aged 30 to 69 years with documented MI not less than six weeks nor more than one year prior to admission to the study. Work capacity level < 7 MET (men) or < 6 MET (women) or a Taylor Manifest Anxiety Scale raw score of 19+ or Zung Self-rating Depression Scale raw score of 40+, or any or all of these.  
**Exclusion criteria:** Presence of unstable cardiovascular condition i.e. congestive heart failure, or requirement of treatment for any physical/psychological reason.  
**N randomised:** total: 106; intervention: 42; comparator (usual care): 29; group counselling: 35 (no data analysed in this review)  
**Diagnosis (% of participants):** MI: 100%  
**Age (mean):** 54  
**Percentage male:** intervention: 90%; comparator: 76%  
**Ethnicity:** 85% white

#### Interventions

**Intervention:** Three one-hour sessions per week over a 12-week period. All exercises were dynamic, involving rhythmic movements against resistance. Half were upper limb (rowing machine, arm wheel, and arm ergometer) and half were lower limb (treadmill, cycle, and step ergometer). Participants exercised upper and lower limbs alternately for four minutes with two minutes of rest in between. The intensity of exercise was determined by heart-rate response, the target level being 85% of the peak exercise heart rate achieved in the first evaluation. If the heart rate was consistently above or below target, the work load was increased or decreased.  
**Components:** exercise.  
**Setting:** supervised in a centre.  
**Exercise programme modality:** e.g. rowing, treadmill, cycle or step ergometer.  
**Length of session:** 1 hour.  
**Frequency:** 3 times a week.  
**Intensity:** Target HR 85% of HR max at exercise tolerance test.  
**Resistance training included?** No.  
**Total duration:** 12 weeks.  
**Co-interventions:** none described.  
**Comparator:** followed up by their physicians and given routine post-MI medical care. Participants were requested to not join a supervised exercise or a formal counselling programme.  
**Co-interventions:** none described.

#### Outcomes

Mortality, non-fatal MI.

#### Source of funding

National Institute of Handicapped Research, Department of Education, Washington, DC.

Cochrane Database of Systematic Reviews

Sun 2016

N randomised: total: 70; intervention: 35; comparator: 35

Diagnosis (% of participants): intervention: stable angina pectoris (57.1%), asymptomatic post MI (20%), old MI (28.6%), post PCI (25.7%); comparator: stable angina pectoris (51.4%), asymptomatic post MI (5.7%), old MI (22.9%), post PCI (42.9%), post CABG 5.7%.

Age (mean, range): intervention: 65, range 61-72; comparator: 65, range 60-70.

Percentage male: intervention: 54%; comparator: 69%

Ethnicity: NR

Interventions

Intervention:

1) Exercise mode: Walk or jog on the exercise board (T2100 exercise board equipped with 12 leads ECG and blood pressure monitoring)

2) Exercise intensity: The heart rate reserve method was used combining self-perceived fatigue of the participant to reach 50% to 80% of the maximum exercise intensity or Borg rate of perceived exertion at 12 to 16

3) Exercise time: 30 - 60 mins, including 5 - 10 mins warm-up and relaxation exercises

4) After discharge, participants can choose one or more kinds of aerobic exercise rehabilitation from walking, jogging, walking on the treadmill, cycling, swimming, and playing badminton etc. for 3 to 5 times a week.

Components: exercise plus education.

Setting: centre-based (3 months), home-based (9 months)

Exercise programme modality: walking, jogging, walking on the treadmill, cycling, swimming, and playing badminton etc.

Length of session: 30-60 minutes.

Intensity: 50-80% heart rate reserve or RPE 12-16.

Resistance training included? NR

Total duration: 12 months.

Co-interventions: None described

Comparator: “conventional treatment” including “health education and standard medication”

Co-interventions: none described.

Outcomes

No relevant outcomes reported

Source of funding

Military Medicine and Geriatrics of the Headquarters of the General Staff (ZCWS14C25)

Conflicts of interest

Not reported

Notes

Study reports outcomes of BMI, BP, lipids, smoking, and no CONSORT flow diagram reported.

Exercise-based cardiac rehabilitation for coronary heart disease (Review)
### Study characteristics

**Methods**

- **Study design:** single-centre RCT
- **Country:** USA
- **Dates participants recruited:** NR
- **Maximum follow-up:** 24 months

**Participants**

- **Inclusion criteria:** Postmenopausal women with coronary heart disease, defined as atherosclerosis, MI, percutaneous transluminal coronary angioplasty, and/or coronary bypass graft surgery.
- **Exclusion criteria:** Other life-threatening illnesses, infarction during the preceding 6 weeks, receiving streptokinase or alteplase, or being scheduled for bypass surgery.
- **N randomised:** total: 25; intervention: 14; comparator: 11
- **Diagnosis (% of participants):**
  - CHD: 100%
  - Previous AMI: 52%
  - PCI: 36%
  - CABG: 28%
- **Age (mean ±SD):** intervention: 64 ± 10; comparator: 63 ± 11
- **Percentage male:** 0%
- **Ethnicity:** 92% white

**Interventions**

- **Intervention:** Daily group physical activity sessions included warm-up, walking or aerobics, and a cool-down. Participants were individually prescribed exercise intensity based on their treadmill exercise test performance. Following the retreat, the intervention exercise programme required participants to engage in a 1-hour session per day at least 3 days each week.
- **Components:** exercise, education and psychological support.
- **Setting:** supervised sessions in a centre followed by home.
- **Exercise programme modality:** walking or aerobics.
- **Length of session:** 1 hour.
- **Frequency:** daily and then at least 3 days a week.
Intensity: individually prescribed.
Resistance training included? no.

Total duration: 24 months.

Co-interventions: Participants randomised to the PrimeTime programme began the intervention with a 7-day retreat. Women were encouraged to bring their partner. As well as physical activity, the daily schedule included cooking classes, instruction in stress-management techniques including Hatha Yoga stretches, progressive deep relaxation, deep breathing, meditation, group support, smoking cessation and directed or receptive imagery. Twice-weekly 4-hour meetings followed the retreat with each meeting following a sequence similar to the retreat schedule.

Comparator: usual care.

Co-interventions: none described.

Outcomes Health-related quality of life: SF-36 at 24 months

Source of funding National Heart, Lung, and Blood Institute

Conflicts of interest NR

Uddin 2020

Study characteristics

Methods Study design: Quasi-RCT (single centre)

Country: Bangladesh

Dates participants recruited: July 2012 - July 2013

Maximum follow-up: 12 months
Participants

**Inclusion criteria**: participants admitted for elective CABG surgery, aged between 25-65 years and understood Bangla.

**Exclusion criteria**: Admission for emergency CABG surgery or revision CABG surgery, any neurological problems or severe comorbidities, or they were not planning to stay in Bangladesh for ≥ 1 year after CABG surgery.

**N randomised**: total: 142; intervention: 71; comparator: 71

**Diagnosis (% of participants)**: post-CABG (100%).

**Age (mean ± SD)**: intervention: 54 ± 6; comparator: 55 ± 6

**Percentage male**: intervention: 66 (93%); comparator: 63 (89%)

**Ethnicity**: NR

Interventions

**Intervention**: participants participated in a 45-min CR class (groups of 6-10, 7-8 days after surgery) in the hospital and were provided with an educational booklet in Bangla. In the class, participants were encouraged to comply with and have knowledge about medical advice, given information about the home exercise program, stress management, smoking cessation, alcohol intake and diet, encouraged to resume everyday activities and social interaction.

The booklet described a home exercise training program including upper- and lower-limb exercises, breathing exercises, chest movements and aerobic exercise (walking program). Educational information provided about safe levels of activity, details of personal risk factors, useful telephone numbers, when to seek medical advice, and how to manage recurrent breathlessness or chest pain.

Participants received a monthly telephone call for 12 months from a qualified physiotherapist trained by the research team regarding the CR advice booklet and exercise program. The physiotherapist answered any participant questions and reminded them to follow the CR program, and attend their next hospital appointment.

**Components**: exercise plus education.

**Setting**: home-based (with one initial centre-based session)

**Exercise programme modality**: Upper and lower limb exercises, breathing and chest exercises, walking.

**Length of session**: 30 minutes.

**Frequency**: 4 sessions per week.

**Intensity**: RPE 11-13.

**Resistance training included**? Not clear.

**Total duration**: 12 months.

**Co-interventions**: None described

**Comparator**: Usual care – conventional hospital discharge care including drug treatment, post-surgical information (precautions i.e. do not lift, pull or push heavy objects or weight > 5kg, lie in a supine position in bed), dietary advice from a dietician and routine follow-up hospital visits.

**Co-interventions**: None described.

Vermeulen 1983

**Study characteristics**

**Methods**  
**Study design:** single-centre RCT  
**Country:** Netherlands  
**Dates participants recruited:** NR  
**Maximum follow-up:** 5 years  
Randomised 4 to 6 weeks post-MI after exercise tolerance test.
### Participants

**Inclusion criteria**: Men (aged 40 to 55 years) who were hospitalised within 6 hours after onset of complaints of first myocardial infarction.

**Exclusion criteria**: Combination of bundle branch block and anterior myocardial infarction

**N randomised**: total: 98; intervention: 47; comparator: 51

**Diagnosis (% of participants)**: MI: 100%

**Age (mean ± SD)**: intervention: 49.4 ± 3.7; comparator: 49.1 ± 4.5

**Percentage male**: intervention: 100%; comparator: 100%

**Ethnicity**: NR

### Interventions

**Intervention**: The rehabilitation consisted of multidisciplinary intervention (physical, social, psychological).

**Components**: exercise, psychological support.

**Setting**: Centre

**Exercise programme modality**: NR

**Length of session**: NR

**Frequency**: NR

**Intensity**: NR

**Resistance training included?**: NR

**Total duration**: 6 - 8 weeks.

**Co-interventions**: none described.

**Comparator**: usual care.

**Co-interventions**: none described.

### Outcomes

Mortality, non-fatal MI.

### Source of funding

Prevention Fund, the Hague.

### Conflicts of interest

NR

### Notes

Study authors conclude that cardiac rehab benefits participants after MI due to direct effect on myocardial perfusion and to lowering of cholesterol levels.

**Vermeulen 1983 (Continued)**

Exercise-based cardiac rehabilitation for coronary heart disease (Review)

Copyright © 2021 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
### Study characteristics

#### Methods

- **Study design:** Multicentre RCT (3 sites)
- **Country:** Norway
- **Dates participants recruited:** NR
- **Maximum follow-up:** 2 years

#### Participants

- **Inclusion criteria:** participants admitted to hospital for acute MI, unstable angina pectoris or after coronary artery bypass grafting.
- **Exclusion criteria:** none described.
- **N randomised:** total: 197; intervention: 98; comparator: 99
- **Diagnosis (% of participants):**
  - AMI: 37%
  - UAP stabilised: 2%
  - PCI: 20%
  - CABG: 25%
- **Age (mean ± SD):** intervention: 54 ± 8; comparator: 55 ± 8
- **Percentage male:** intervention: 91%; comparator: 84%
- **Ethnicity:** NR

#### Interventions

- **Intervention:** The first phase lasted for 6 weeks with supervised physical exercise in addition to a regular group meeting twice a week. Each training session started with 15 min of warm up followed by 20 min of dynamic endurance training, 10 min of active cool-down activities and finally 10 min of stretching and relaxation. Large muscle groups in the arms and legs were used simultaneously to achieve higher exercise intensity (11-13 on the Borg scale). No weight lifting took place. This was followed by 9 weeks of supervised physical exercise twice weekly. The intensity level was increased to achieve an exertion rate equal to jogging (13-15 on the Borg scale). Participants were then encouraged to perform regular training at home.
- **Components:** exercise, education and psychological support.
- **Setting:** supervised, group sessions in a centre.
- **Exercise programme modality:** "dynamic endurance training".
- **Length of session:** 55 min.
- **Frequency:** twice a week.
- **Intensity:** RPE 11-13 on the Borg Scale, increased to 13-15 after 6 weeks.
- **Resistance training included?** No.
- **Total duration:** 15 weeks.
Co-interventions: The multidisciplinary CR of "Heart School" comprised dietary advice, smoking cessation, physical activity counselling, risk factor management, psychosocial management and health education.

Comparator: Usual care: participants received usual standardised nurse-based information on CHD in general and lifestyle measures.

Co-interventions: none described.

Wang 2012

Study characteristics

Methods

Study design: Multicentre RCT (2 sites)

Country: China

Dates participants recruited: Oct 2005 to April 2007

Maximum follow-up: 6 months

Participants

Inclusion criteria: Inclusion criteria comprised a documented diagnosis of acute MI, the ability to speak and read Chinese, a return to living at home after hospital discharge, availability for telephone follow-up, and availability for meetings after hospital discharge.

Exclusion criteria: Exclusion criteria comprised a known history of major psychiatric illness, pre-existing mobility problems, unstable angina, severe complications such as uncontrolled arrhythmias
or heart failure, and other conditions that could be aggravated by exercise, such as a resting systolic blood pressure (BP) > 200 mmHg or a resting diastolic BP > 110 mmHg.

N randomised: total: 160; intervention: 80; comparator: 80

Diagnosis (% of participants): AMI: 100%

Age (mean ± SD): intervention: 57.3 (± 8.6); comparator: 58.3 (± 10.4)

Percentage male: intervention: 85.3%; comparator: 81.5%

Ethnicity: NR

Interventions

**Intervention:** A 6-week, home-based rehabilitation programme using a self-help heart manual given to the rehab participants just before discharge from hospital. The manual was similar to the UK Heart Manual but incorporated appropriate sociocultural components such as tai chi, qi gong, and Chinese diet.

Section 1 consists of 6 weekly topics on health education.

Section 2 answers commonly asked questions about medication, PCI, anxiety and depression etc.

Section 3 presents information on normal values of cardiac physiological risk parameters.

The rehabilitation group received the manual and the introductory session in addition to usual care.

The exercise component of the manual is not described in this paper, and there is no reference to its description elsewhere.

**Components:** exercise plus education.

**Setting:** home.

**Exercise programme modality:** not described.

**Length of session:** not described.

**Frequency:** not described.

**Intensity:** not described.

**Resistance training included?** not described.

**Total duration:** not described.

**Co-interventions:** participants in both groups were telephoned by the principal researcher 3 weeks after discharge. For the rehabilitation group, the researcher checked the participants’ progress, encouraged adherence to exercise, and helped solve problems that had arisen using the manual. This consultation lasted approximately 30 minutes, with contact designed to promote participant confidence and self-management, and minimise dependency and the possibility that the nurse could influence outcomes.

**Comparator:** The usual care group received instructions on taking medications, information leaflets about cardiac risk factors, a healthy diet, and smoking cessation, and a follow-up appointment.

**Co-interventions:** The researcher devoted an equal amount of time to telephone contact with the control group, giving general advice on any problems encountered and encouraging and supporting appropriate actions.

| Selective reporting (reporting bias)      | Low risk           | All outcomes described were reported for all time points.                               |

West 2012

Study characteristics

Methods

**Study design:** Multicentre RCT (14 sites)

**Country:** England and Wales, UK

**Dates participants recruited:** August 1997 to April 2000

**Maximum follow-up:** 7 to 9 years

Participants

**Inclusion criteria:** Admission to hospital with a principal primary diagnosis of acute MI (two of the three standard criteria ‘typical history’, electrocardiographic features and cardiac enzymes), discharged home within 28 days, local resident and able to give informed consent with no age or gender restrictions.

**Exclusion criteria:** Physical frailty, mental confusion, serious co-existing disease, communication difficulty, previous cardiac rehabilitation and discharged to hospice or another hospital.

**N randomised:** total: 1813; intervention: 903; comparator: 910

**Diagnosis (%) of participants:** Acute MI: 100%

**Age (mean ± SD):** intervention: 64.2 ± 11.2; comparator: 64.7 ± 10.9

**Percentage male:** intervention: 72.6%; comparator: 74.4%

**Ethnicity:** NR

Interventions

**Intervention:** Exercise training was the largest component, typically occupying half of the available time including warm up and cool down, and used exercise equipment in physiotherapy gyms. Relaxation was primarily physical following ‘cooling down’ from exercise with little or no ‘stress management’ training.
Components: exercise plus education plus psych.

Setting: centre-based supervised programmes which varied by centre.

Exercise programme modality: varied by centre.
Length of session: averaged 20 hours over 6-8 weeks.
Frequency: weekly or bi-weekly.
Intensity: NR
Resistance training included? NR

Total duration: 6-8 weeks.

Co-interventions: The programmes comprised exercise training, health education about heart, heart disease, risk factors and treatment, counselling for recovery and advice for long-term secondary prevention. All involved at least one other discipline (exercise physiologist, dietician, pharmacist, health promotion specialist, psychologist, counsellor, social worker, physician and/or cardiologist).

Comparator: All participants in the trial (and in the ‘elective hospitals’ comparison) had similar care in all respects other than referral to cardiac rehabilitation, receiving available explanatory booklets, being advised to see their general practitioner (GP) and attend routine outpatient follow-up, with referral for further cardiac investigations or interventions as appropriate.

Co-interventions: none described.

Outcomes
Mortality, MI, revascularisations, hospitalisation, HRQoL.

Source of funding
NHS Research and Development Programme (northern region) and the Heart Research Fund for Wales.

Conflicts of interest
None declared.

Notes
An additional 331 participants were entered in two matched pairs of ‘elective rehabilitation’ and ‘elective control’ hospitals; 197 to rehabilitation and 134 to control. These participants did not contribute any data used in the systematic review.

- **Maximum follow-up:** 3 years
  - Participants randomised on discharge from hospital.

**Participants**

- **Inclusion criteria:** Men < 65 years with first or consecutive MI.
- **Exclusion criteria:** NR
- **N randomised:** total: 3184; intervention: 1655; comparator: 1529
- **Diagnosis (% of participants):** MI: 100%
- **Age (years):** intervention: 52.3; comparator: 53.5
- **Percentage male:** intervention: 100%; comparator: 100%
- **Ethnicity:** NR

**Interventions**

- **Intervention:** Comprehensive programme dependent on local provision. Physical training was not compulsory but was strongly recommended.
- **Components:** exercise, education and psychosocial support.
- **Setting:** centre.
- **Exercise programme modality:** NR
- **Length of session:** NR
- **Frequency:** NR
- **Intensity:** NR
- **Resistance training included?** NR
- **Total duration:** 6 weeks.
- **Co-interventions:** The intervention had to be at the highest possible level available locally. It had to be comprehensive, with the aim of improving health and reducing IHD risk. It comprised treatment of health failure, arterial hypertension etc, risk factor modification, weight loss and improving physical working capacity.
- **Comparator:** usual care.
- **Co-interventions:** none described.

**Outcomes**

**Source of funding**

- WHO Regional Office for Europe and the Ministries of Health of the participating member states.

**Conflicts of interest**

**Notes**

- Methodological problems with the execution of the study allowed only death and re-infarction to be successfully used as end points.

### Wilhelmsen 1975

**Study characteristics**

**Methods**
- **Study design:** single-centre RCT
- **Country:** Sweden
- **Dates participants recruited:** 1968-1970
- **Maximum follow-up:** 5 years
- Participants randomised on discharge.

**Participants**
- **Inclusion criteria:** All participants born in 1913 or later who suffered a MI during the period 1968-1970 and were discharged alive from the hospital.
- **Exclusion criteria:** none described.
- **N randomised:** total: 315; intervention: 158; comparator: 157
- **Diagnosis (% of participants):** MI: 100%
- **Age (years):** intervention: 50.6; comparator: 50.6
- **Percentage male:** intervention: 87%; comparator: 90%
- **Ethnicity:** NR

**Interventions**
- **Intervention:** The training programme started 3 months after the MI. The programme at the hospital consisted of three supervised half-hour training sessions a week. It included dynamic work, such as calisthenics, cycling, and running in an interval programme with individualised intensity. If a participant found it difficult to attend the hospital for training, then individualised programmes were developed for training at home or in the workplace.
- **Components:** exercise.
- **Setting:** supervised in a centre.
- **Exercise programme modality:** e.g. cycling, running.
### Wilhelmsen 1975 (Continued)

**Length of session:** 1/2 hour.

**Frequency:** three times a week.

**Intensity:** 144 ± 18 beats/min; 80% of their heart rate increasing capacity (if no sign of cardiac limitation); 136 ± 19 beats/min in mean highest training heart rate (if limited by angina pectoris).

**Resistance training included?** Callisthenics.

**Total duration:** NR - see notes below.

**Co-interventions:** At discharge from hospital, all participants were given general recommendations about gradually increasing physical activity during the convalescence period.

**Comparator:** usual care.

**Co-interventions:** as above.

### Study characteristics

#### Methods

**Study design:** single-centre RCT

**Country:** China

**Dates participants recruited:** January 2014 - September 2015

**Maximum follow-up:** 6 months

#### Participants

**Inclusion criteria:**
1) Meet the diagnostic criteria of the coronary heart disease, referring to the 13th edition of the Practice Internal Medicine (a Chinese medical textbook)

2) From 39 to 70 years old

3) Participants who are easy to communicate with

4) Long-term resident in the local area and completed the informed consent

5) Hemodynamics were stable after PCI

**Exclusion criteria:**

1) People with serious arrhythmia (such as atroventricular block, atrial fibrillation, ventricular tachycardia, etc.), myocarditis, cardiomyopathy, and the installation of a pacemaker

2) People with serious cardiac insufficiency (NYHA class IV), left ventricular ejection fraction < 30%

3) People with severe cerebrovascular diseases (such as cerebral infarction and cerebral haemorrhage)

4) People with serious pulmonary diseases (such as chronic obstructive pulmonary disease, emphysema, pulmonary heart disease, etc.)

5) People with rheumatoid arthritis, osteoarthritis, muscles and other diseases that seriously affect physical activity

6) People with serious organic diseases and abnormal liver and kidney function

**N randomised:** total: 130; intervention: 65; comparator: 65

**Diagnosis (% of participants):** post-PCI patients with unstable angina (100%).

**Age (mean ± SD):** intervention: 56.4 ± 8.1; comparator: 58.6 ± 8

**Percentage male:** intervention: 46 (79%); comparator: 47 (78%)

**Ethnicity:** NR

<table>
<thead>
<tr>
<th>Interventions</th>
<th>Intervention</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>There are 2 stages. The first stage is after patients had PCI until they were discharged, the second is from when they were discharged to the third month after PCI. The first stage:</td>
</tr>
<tr>
<td></td>
<td>1) The first day after PCI, advise patients to walk for 200 meters per time for 5 times a day.</td>
</tr>
<tr>
<td></td>
<td>2) The second day after PCI, advise patients to walk for 300 meters per time for 5 times a day.</td>
</tr>
<tr>
<td></td>
<td>3) The third day after PCI, advise patients to walk for 500 meters per time for 5 times a day. They can also go up and down a flight of stairs depending on their own conditions. The second stage:</td>
</tr>
<tr>
<td></td>
<td>1) After the patients discharged in the first month after PCI:</td>
</tr>
<tr>
<td></td>
<td>Walking 30 to 40 mins with the speed of 65-75 m/min for 3 times a week; or, walking for 10 to 15 mins 3 times a day with a 5-min break among them for 3 times a week; or, walking for 15 to 20 mins twice a day with a 5-min break between them for 3 times a week. After each time of walking, guide patients to do some chest enlargement, slow leg lift and upper limb extension exercise, so that the patients’ heart rate, blood pressure can be back to normal levels before walking.</td>
</tr>
<tr>
<td></td>
<td>2) 1 to 2 months after PCI:</td>
</tr>
</tbody>
</table>
|               | The exercise mode was repeated in alternations of walking and brisk walking. Walk for 90 seconds, followed by brisk walking for 45 s. Repeat above. The walking speed is at 65-75 m/min, and the brisk walk-
ing speed is at 85-95 m/min. This exercise was 30~40 min each time for 3 times a week. After each time, patients would have relaxation exercise for 10 to 15 mins.

3) 2 to 3 months after PCI:

A set of exercise rehabilitation, includes a combination of upper limb and lower limb exercise, combined with resistance training of elastic band and balance training on yoga mat. The whole process can be divided into the pre-activity stage (8-10 min), the exercise march stage (30-40 min) and the recovery stage (10-15 min).

**Components:** exercise only.

**Setting:** centre-based

**Exercise programme modality:** Mostly walking, some upper and lower limb exercise, resistance training and balance exercises.

**Length of session:** around 30-40 mins up to 1 hour (length increases over time).

**Frequency:** 3 times per week (stage 2).

**Intensity:** walking speed 65-75 m/min up to 85-95 m/min (brisk walking).

**Resistance training included?** Yes, stage 2 included resistance training with elastic bands.

**Total duration:** 3 months.

**Co-interventions:** None described

**Comparator:** “All patients received conventional drug therapy and post-PCI knowledge education”

**Co-interventions:** none described.

## Study characteristics

### Methods

**Study design:** single-centre RCT  
**Country:** China  
**Dates participants recruited:** NR  
**Maximum follow-up:** 2 years

### Participants

**Inclusion criteria:** Obese participants with CHD who had either recent AMI or had undergone elective PCI in last 6 weeks.  
**Exclusion criteria:** Post-infarction angina without revascularisation procedures, significant valvular stenosis, active pericarditis or myocarditis, severe uncontrolled hypertension, physical problems that precluded exercise training, cognitive impairment, malignancies that limited life span to 1 year.  
**N randomised:** total: 112; intervention: 72; comparator: 40  
**Diagnosis (% of participants):**  
- AMI: 64%  
- PCI: 36%  
**Age (mean ±SD):** intervention: 62.3 ± 11.2; comparator: 61.2 ± 10.2  
**Percentage male:** intervention: 82%; comparator: 75%  
**Ethnicity:** NR

### Interventions

**Intervention:**  
Phase 1 was an inpatient ambulatory programme that lasted 7 to 14 days.  
Phase 2 was a 16-session, twice weekly, outpatient exercise and education programme lasting for 8 weeks. Each session included 1 hour of education class followed by 2 hours of exercise training. The first hour of training focused on aerobic CV training with a target intensity of 65% to 85% of maximal aerobic capacity. This included treadmill, ergometry, rowing, stepper, arm ergometry, and dumbbell and weight training. The next hour was conducted by an occupational therapist in which domiciliary or vocational environment-focused training was performed.  
Phase 3 was a community-based home exercise programme for another 6 months.  
**Components:** exercise and education.  
**Setting:** centre followed by home.  
**Exercise programme modality:** treadmill, ergometry, rowing, stepper, arm ergometry, and dumbbell.  
**Length of session:** 2 hours (for 8 weeks) then unspecified at home.  
**Frequency:** twice a week (for 8 weeks) then unspecified at home.  
**Intensity:** 65% to 85% of maximal aerobic capacity.  
**Resistance training included?** Weight training.  
**Total duration:** 8 1/2 months.  
**Co-interventions:** Phase 4 was a long-term follow-up programme until the end of 2 years, which included half-yearly monitoring of lipid profiles, and again stressed the importance of regular exercise and risk factor modification.  
**Comparator:** conventional medical therapy.
Yu 2003 (Continued)

**Co-interventions**: The control group attended a 2-hour talk that explained CHD, the importance of risk factor modification, and potential benefits of physical activity, but without undergoing an outpatient exercise training programme.

**Study characteristics**

**Methods**
- **Study design**: single-centre RCT
- **Country**: China
- **Dates participants recruited**: January 2010 - December 2012
- **Maximum follow-up**: 6 months

**Participants**
- **Inclusion criteria**: participants admitted to the outpatient clinic after successful PCI for ST-segment elevated MI between January 2010 and December 2012.
- **Exclusion criteria**: A large area of myocardial infarction, heart failure, acute systemic illness, systolic BP > 180 mmHg at rest, diastolic BP > 110 mmHg at rest, acute metabolic disorders, uncontrolled malignant arrhythmia, and skeletal vascular disease.
- **N randomised**: total: 130; intervention: 65; comparator: 65
- **Diagnosis (% of participants)**: post-PCI for STEMI (100%).
- **Age (mean ± SD)**: intervention: 70.3 ± 10.7; comparator: 69.8 ± 10.4
- **Percentage male**: intervention: 59 (90.8%); comparator: 54 (83.1%)
- **Ethnicity**: NR

**Interventions**
- **Intervention**: GP formulated individual aerobic exercise program that could be performed in the participants' homes or at specialised rehabilitation facilities in the community. Phase II CR optimally initiated within 2 weeks of discharge (lasting 6-8 weeks). Most available form of exercise was walking, but other forms of aerobic exercise were acceptable. HR < 130 bpm or resting HR plus 30 bpm, or RPE 11-15. Participants exercised 2-3 times per week, interval or continuous training for 15-30 minutes. Phase III started from month 3 to 1 year. Target HR 60-75% max HR, RPE 12-16, 30-45 minutes per session, no less than 3-5 times per week.
- **Components**: exercise only.
- **Setting**: home- or centre-based (community), participant choice
- **Exercise programme modality**: walking.
- **Length of session**: 15-30 minutes, increasing to 30-45 minutes.
- **Frequency**: 2-3 sessions per week, increasing to 3-5.
- **Intensity**: < 130 bpm or RPE 11-13, increasing to 60-75% max HR or RPE 12-16.
Zhang 2018 (Continued)

**Resistance training included?** No.

**Total duration:** 12 months.

**Co-interventions:** None described

**Comparator:** Usual care and conventional drug therapy post-PCI

**Co-interventions:** none described.

CHD: coronary heart disease  
CR: cardiac rehabilitation  
RCT: randomised controlled trial  
NR: not reported  

**Characteristics of studies awaiting classification** [ordered by study ID]
### Aronov 2006

**Methods**
- **Study design:** NR
- **Country:** Russia
- **Follow-up:** 6 months

**Participants**
- **Inclusion criteria:** Acute coronary event (acute myocardial infarction, unstable angina, CABG)
- **Exclusion criteria:** NR
- **N randomised:** total: 373; intervention: 188; comparator: 185

**Interventions**
- **Intervention:** Standard therapy plus exercise programme - moderate exercise for 1 hour, 3 times per week for 1 year
- **Comparator:** Standard therapy

**Outcomes**
- Not clear if any outcomes of interest were measured or reported

**Notes**
- Unable to access full text

---

### Belardinelli 2007

**Methods**
- **Study design:** RCT
- **Country:** NR
- **Dates participants recruited:** January 2002 to November 2004
- **Planned follow-up:** 5 years

**Participants**
- **Inclusion criteria:** NR
- **Exclusion criteria:** NR
- **N randomised:** total: 259
- **Diagnosis (% of participants):** people with CAD who underwent PCI or CABG
- **Age (years):** Intervention: 56±8 years; comparator: 58±8 years

**Interventions**
- **Intervention:** Group CR combining exercise training 60% peak VO$_2$ 3 times a week for 8 weeks with nutrition counselling and standard medication
- **Comparator:** No CR

**Outcomes**
- MI, PCI, CABG, hospitalisation, cardiac death

**Notes**
- Abstract only, with incomplete reporting of study characteristics and outcome data. Full trial report not published.

---

### Bubnova 2015

**Methods**
- **Study design:** RCT
- **Planned follow-up:** 1 year
### Bubnova 2015 (Continued)

**Participants**
- **N randomised:** total: 62; intervention: 31; control: 31
- **Diagnosis (% of participants):** PCI (100%)
- **Age (years):** Intervention: 56±7 years; comparator: 53±8 years

**Interventions**
- **Intervention:** Program of moderate intensity physical training (60 min per session, 3 times per week for 6 weeks) plus education and standard therapy
- **Comparator:** Educational program and standard therapy

**Outcomes**
- "Cardiovascular events" (not clear what these include)

**Notes**
- Conference abstract; triallists did not respond to repeated requests for further information

### Chen 2020

**Methods**
- **Study design:** RCT

**Participants**
- **Inclusion criteria:** Participants with a clinical diagnosis of AMI, aged 18 to 80 years, performed PCI, and signed a consent form.
- **Exclusion criteria:** Current participation in any other behavioural or pharmacological study or instructor-led exercise program, cardiogenic shock, severe heart failure (NYHA class IV or LVEF ≤ 35%), malignant arrhythmia (ventricular fibrillation, ventricular tachycardia, and frequent ventricular premature beats), or active bleeding. People with underlying conditions such as bone and joint disease or nervous system disorders that would impede full participation in the study and unavailability during the study period.

**Interventions**
- **Intervention:** Baduanjin sequential therapy (BST) beginning 2 days after surgery (30 min/session, twice per day, 3 days). After discharge, participants did standing Baduanjin exercises 30 min/session, five times per week for 24 weeks. Participants were provided picture-based educational brochure, and telephone follow-ups were provided to reinforce participants’ adherence to the follow-up assessments.
- **Comparator:** requested to maintain original habit of lifestyle

**Outcomes**
- HRQoL

**Notes**
- The authors were contacted to clarify an unclear section within the methods describing the treatment received by the control group, but no response received.

### Ghroubi 2012

**Methods**
- **Study design:** RCT
- **Country:** NR
- **Dates participants recruited:** NR
- **Planned follow-up:** 2 years

**Participants**
- **Inclusion criteria:** people with MI who underwent coronary stenting
- **Exclusion criteria:** NR
- **N randomised:** total: 68; intervention: 30; comparator: 38

Marques-Sule 2016 (Continued)

Outcomes
No outcomes of interest reported in either conference abstract

Notes
Unable to locate full text

NCT00725088

Methods
Study design: RCT
Follow-up: 1 year

Participants
Inclusion criteria: Clinical diagnosis of ST-elevated MI, heart function class I-II (Killip classification), agree to take cardiopulmonary exercise testing before discharge, signature of informed consent document

Exclusion criteria: History of MI, acute MI with severe complications (pulmonary edema, severe cardiac arrhythmia or cardiogenic shock), atrial fibrillation, other severe diseases such as HIV infection, malignant tumour or chronic diseases of liver kidney or pulmonary, not capable of exercise training

Interventions
Intervention: exercise training
Comparator: NR

Outcomes
Cardiac mortality, MI, revascularisation, hospitalisation

Notes
Triallists contacted for update on status of study, but no response received

Pater 2000

Methods
Study design: RCT
Country: Norway
Follow-up: 3 years

Participants
Inclusion criteria:
- Males and females aged 40 to 85 years,
- Unequivocal hospital-verified, definite AMI less than 3 months ago
- People with a recent ACS (that is, established CHD with a stabilised condition after a recent unstable episode)
- PTCA patients (more than 4 weeks after a PTCA)
- CABG patients (more than 4 weeks after a CABG)
- Ambulatory patients who have signed a declaration of consent

Exclusion criteria:
- Unstable angina pectoris
- Scheduled angiography
- Clinically significant heart failure
- Severe hypertension
- Symptoms of orthostatic hypertension or a supine systolic blood pressure of 90 mmHg or lower
- Severe arrhythmias persisting after the acute phase of the MI
- Psychoneurotic disorders (depression and/or anxiety)
Pater 2000 (Continued)

- Severe obstructive airway disease with permanent respiratory insufficiency
- Uncontrolled diabetic mellitus
- Severe orthopaedic disability
- Serum creatinine more than double the local upper normal limit
- Alanine amino-transferase or aspartate amino-transferase more than three times the local upper limit (in the context of known liver disease)
- Presence of any condition that limits life expectancy (e.g. cancer or haematological diseases)
- Problems expected with compliance or follow-up
- Participation in another trial or study during the past 30 days
- Stroke with severe physical disability

**Interventions**

**Intervention:** structured secondary prevention programme including patient education, brief counselling, and systematic physical training tailored to each individual. The exercise programme consists of 8 weeks of supervised outpatient physical training.

**Comparator:** conventional care

**Outcomes**

HRQoL

**Notes**

Authors did not respond to repeated requests for study update.

Pomeshkina 2014

**Methods**

**Study design:** RCT

**Follow-up:** 1 year

**Participants**

**Inclusion criteria:** NR

**Exclusion criteria:** NR

**N randomised:** total: 64; intervention: 29; control: 35

**Diagnosis (% of participants):** CABG (100%)

**Mean age:** 54.7±4.6 years

**Interventions**

**Intervention:** Common medical rehabilitation programme with long-term (3 months) cycling training

**Comparator:** Common medical rehabilitation (medication, lifestyle modifications)

**Outcomes**

Unclear if any outcomes of interest were measured or reported

**Notes**

Triallists did not respond to requests for study updates

Rymuza 2019

**Methods**

**Study design:** RCT

**Follow-up:** 12 months

**Participants**

**Inclusion criteria:** participants with ACS, age > 75 years, after PCI

**Exclusion criteria:** NR
### Rymuza 2019

**N randomised:** total: 51; intervention: 25; control: 26  
**Diagnosis (% of participants):** PCI (100%)  
**Mean age:** 80 years

Tai Chi for stress and cardiovascular function in patients with coronary heart disease and/or hypertension: a randomised controlled trial

**Methods**

RCT with waiting-list control

**Participants**

**Inclusion criteria:**

1. Equal to or greater than 40 years of age, regardless of gender;
2. With documented diagnosis of CHD (myocardial infarction, angina or revascularisation) with severity of angina class I to II according to the Canadian Cardiovascular Society functional classification, and/or with established diagnosis of hypertension according to the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure;
3. Ability to perform prescribed Tai Chi program;
4. Willing to complete the 24-week Tai Chi intervention;
5. Not practicing Tai Chi in the past 6 months;
6. Ability to speak and read Chinese or English fluently;
7. Willing to sign a written informed consent.

**Exclusion criteria:**

1. Pregnancy
2. Previous or current psychological disorders not associated with depression or anxiety
3. End-stage congestive heart failure
4. Permanent bed-bound status
5. Unstable abdominal, thoracic or cerebral aneurysm
6. Acute myocarditis, pericarditis, pulmonary embolus or pulmonary infarction
7. Significant limitation of physical activity for reasons other than CHD
8. Participation in a clinical trial for an experimental drug within the last 30 days before the study

**Interventions**

**Intervention:** the intervention group will be offered a standardised Tai Chi intervention over a period of 24 weeks, consisting of a 12-week intensive Tai Chi intervention and a 12-week sustained Tai Chi intervention.

**Comparator:** participants assigned to the waiting-list control group will be instructed to maintain their routine activities and not to begin any new exercise programs during their study participation. These participants will be offered an equivalent 12-week intensive Tai Chi intervention and 12-week sustained Tai Chi intervention at the termination of the study, provided the Tai Chi intervention in the treatment is proved to be safe (no severe adverse events directly associated with Tai Chi).

**Outcomes**

HRQoL, adverse events

**Starting date**

28 August 2015

Study name: Efficacy of YOGA in Indian patients with coronary artery disease

Methods: RCT

Participants

**Inclusion criteria:**

1. All adults between 30 and 70 years
2. People with acute coronary syndrome who have undergone percutaneous coronary intervention within 2 weeks or
3. People with stable coronary artery disease who have undergone percutaneous coronary intervention in the last 2 weeks
4. People who are willing and able to participate

**Exclusion criteria:**

1. Severe LV dysfunction
2. Unstable arrhythmia
3. Active decompensated heart failure
4. Uncontrolled hypertension (> 180/110)
5. Contraindications to yoga
6. Contraindications to exercise testing or training
7. NYHA IV
8. Incomplete revascularisation

Interventions

**Intervention:** participants undergoing PCI with routine advice on discharge and enhanced usual care (physiotherapy, medications and lifestyle modifications) will be taught yoga, based on the module in the first week of each phase. On non-class days, participants will be motivated to practice yoga sessions at home every day, and their compliance will be ensured telephonically and through a written log. The participants will be encouraged to practice until the end of the follow-up period (3 years).

**Comparator:** participants will be on enhanced usual care after PCI.

Outcomes: MACCE, HRQoL

Starting date: 03 July 2017

Contact information: drgautamsharma12@gmail.com

Notes

---

Study name: Efficacy of yoga-based cardiac rehabilitation on clinical outcomes in post CABG patients: a randomized controlled trial.

Methods: RCT

Participants

**Inclusion criteria:**

1. People willing and able to participate
2. All adults between 35 and 65 years of age
3. People established with double or triple vessel disease planned for elective CABG
d. People with uncomplicated peri-operative course, who are able to perform yoga

**Exclusion criteria:**

a. Emergency CABG  
b. CABG with valve replacement surgeries  
c. LVEF  
d. Acute and chronic renal failure with or without dialysis  
e. Regular yoga practitioners  
f. Physical disabilities precluding yoga practice  
g. Neuro-psychiatric illness  
h. People already exposed to yoga

**Interventions**

**Intervention:** yoga plus conventional medical management which includes physiotherapy, lifestyle modifications and medications  
**Comparator:** conventional medical management

**Outcomes**

HRQoL, MACCE

**Starting date**

10/10/2017

**CTRI/2019/06/019948**

**Study name**

Effect of cardiac rehabilitation in patients undergone myocardial infarction and percutaneous coronary intervention

**Methods**

RCT

**Participants**

**Inclusion criteria:**

1. 18 to 80 years of age  
2. Diagnosed myocardial infarction who have undergone percutaneous coronary intervention not at risk due to other comorbidities.  
3. Willing to give informed consent  
4. Individuals with acute myocardial infarction  
5. Individuals with New York Heart Association (NYHA) functional class I, II & III symptoms

**Exclusion criteria:**

1. Participants with medical conditions which could put them at risk during physical activity testing or training (e.g. angina), or conditions that could limit the participant’s ability to exercise (e.g. severe orthopaedic or neurologic impairments)  
2. Individuals with prior myocardial infarction

**Interventions**

**Intervention:** adapted phase II and phase III of cardiac rehabilitation programme with components of physical activity, education on coronary artery disease and heart-healthy living  
**Comparator:** participants will not receive any supervised physical activity training. Participants will receive routine care for myocardial infarction after undergoing percutaneous coronary intervention according to current guidelines.
**Study name**

 Century Trial, a randomized lifestyle modification study for management of stable coronary artery disease (Century)

**Methods**

 RCT (single centre)

**Participants**

**Inclusion Criteria:**

- Participants must be competent to provide written informed consent.
- Participants must sign an Institutional Review Board (IRB) approved Informed Consent Form (ICF) and HIPAA Authorization prior to the initiation of any study procedures.
- Men and women age ≥ 40
- Appropriate indications for stress perfusion testing:
  - Suspected CAD:
    - Men with any chest pain syndrome and two other risk factors
    - Women > 50 years old with any chest pain syndrome and two other risk factors
    - Asymptomatic men and women > 50 years with at least three other risk factors or coronary calcium agatston score > 400.
  - Diabetic men and women and two other risk factors
- Documented known CAD:
  - Men and women with asymptomatic or stable symptoms and known CAD by abnormal catheterisation or prior Single Photon Emission Computed Tomography (SPECT) without revascularisation after > 2 years to evaluate worsening disease; or
  - Men and women with worsening symptoms and known CAD by abnormal catheterisation or prior SPECT/ Positron emission tomography (PET) without revascularisation;
  - Men and women with chest pain syndrome and previous revascularisation
- Asymptomatic men and women > 5 years after coronary artery bypass graft surgery (CABG) or > 2 years after PCI
- Risk factors: diabetes, current or recent cigarette smoking (within the last 12 months), LDL > 130, low HDL < 50 women, HDL < 45 men, history of metabolic syndrome, hypertension (systolic blood pressure (SBP) > 140), family history of premature (< 60 year) CAD, atherosclerotic carotid artery disease OR atherosclerotic peripheral vascular disease (APVD) as defined by ankle-brachial index below 0.9 and/or by abnormal duplex ultrasound, CT angiography, magnetic resonance angiography (MRA) or conventional invasive angiogram or previous revascularisation procedure.
- Framingham's high risk criteria refers to presence of diabetes mellitus with the limitation described above (c) or 10 year absolute coronary heart disease (CHD) risk of > or = 20%.
- Chest pain is defined as 'Typical angina' if Exertional + Retrosternal + relieved with rest or sublingual nitroglycerin (NTG), 'Atypical angina' if only two of the above criteria are present and 'Non-anginal' if one or none of the above are present.

**Exclusion criteria:**

- Age < 40
- Low pretest likelihood of CAD (= not meeting the above criteria)
- Unstable angina high risk (dynamic ST-Twave ECG changes and/or elevated troponin)
- Recent MI ( ≤ 4 weeks)
NCT00756379 (Continued)

- Recent stroke (< 4 weeks)
- CABG or percutaneous coronary intervention (PCI) within the last 6 months
- Severe renal dysfunction as defined by creatinine > 2.0 mg/dL
- Active liver disease or hepatic dysfunction, AST or ALT > x 2 the upper limit of normal (ULN)
- Concomitant valvular heart disease
- Left ventricular ejection fraction (LVEF) < 30%
- Severe systemic hypertension defined as systolic blood pressure (SBP) > 200 mmHg
- Symptomatic sustained or non-sustained ventricular tachycardia
- Morbid obesity defined by body mass index (BMI) > 35
- Severe disability to prevent therapeutic exercise not expected to resolve within 6 months
- Major non-cardiac comorbidity limiting survival or social situation/condition that, in the opinion of the investigator, will preclude the patient from participation in the study follow-up.
- Concurrent or prior (within last 30 days) participation in other research studies using investigational drugs or devices.

Interventions

Intervention:

“P.E.T. guided comprehensive therapy program. The study intervention is comprehensive therapy program for risk factor modification. The comprehensive program of atherosclerotic risk factor modification involves treatment to target lipid levels, blood pressure and diabetes control, smoking cessation, very low fat diet and aerobic exercise program. This is in addition to standard current medical therapy as provided by primary physician. No experimental medications or procedures will be used.” “During the 5 year follow-up they will be educated and guided toward a healthy lifestyle by a dietician, an exercise physiologist/cardiovascular physician specialist.”

Comparator:

“Current standard of care medical management as provided by primary physician.”

Outcomes

Mortality, non-fatal MI, revascularisation, total cost

Starting date

March 2009

Contact information

K. Lance Gould, Professor, Internal Medicine, Cardiology, University of Texas Health Science Center, Houston

Notes

NCT02025257

Study name

Effects of exercise in patients with coronary artery disease aged 80 years or older

Methods

RCT

Participants

Inclusion criteria: clinical diagnosis of acute CAD, aged 80 years or older.
Exclusion criteria: inability to understand or speak Swedish, serious physical or psychological disease interfering with participation in an exercise intervention, patients are already exercising three times or more/week

Interventions

Intervention: exercise

Comparator: NR

Outcomes

HRQoL

### NCT03102346

**Study name**  
efficAcy and Safety of Home-based Cardiac rehabilitation in Chinese Revascularized patients (ASSIST)

**Methods**  
RCT

**Participants**  
**Inclusion criteria:**

1. Age range from 30 to 80.  
2. Coronary artery disease, revascularised with stent deployment.  
3. New York Heart Association (NYHA) classification Class I-III.  
4. Good cognitive level.  
5. Ability to perform aerobic exercise.  
6. Understand and be able to use a mobile smart phone by himself or with help of family members.  
7. Signature of informed consent. The informed consent will be valid for the duration of the trial or until the subject withdraws.

**Exclusion criteria:**

1. Presence of malignant arrhythmias such as ventricular fibrillation outside the acute phase of acute myocardial infarction (AMI) (> 24 h after AMI), ventricular tachycardia, Atrioventricular block of 2nd degree and 3rd degree, atrial fibrillation (AF) in patients with Wolf Parkinson White, fibrillation or paroxysmal atrial flutter with response ventricular quickly and haemodynamic deterioration, premature ventricular contractions increases during exertion, paroxysmal supraventricular tachycardia uncontrolled.  
2. Hypotensive response to exercise.  
3. Acute myocardial infarction within 2 weeks.  
4. Poorly controlled hypertension baseline, hyperglycaemia, respiratory failure.  
5. Severe pulmonary hypertension.  
6. Acute phase of heart failure.  
7. Pathology of musculoskeletal, neurological or breathing that impair the ability of prolonged ambulation.  
8. Pregnant women.  
9. Subjects unable to give informed consent.

**Interventions**  
**Intervention:** home-based cardiac rehabilitation  
**Comparator:** no instructed exercise training

**Outcomes**  
MACCE, hospitalisation, HRQoL

| Participants | **Inclusion criteria:**  
  - age over 18 and below 70  
  - completed revascularization in participants with stable or unstable angina or after myocardial infarction without ST-segment elevation (NSTEMI)  
  - in participants with suspected myocardial scars, MRI will be recommended to confirm myocardial viability  
  - eligibility to participate in a program of early cardiac rehabilitation  
  - signed informed consent form  
  - the ability to use telerehabilitation system  
  **Exclusion criteria:**  
  - acute myocardial infarction with ST segment elevation/new onset of left bundle branch block (LBBB)  
  - suboptimal (not completed) revascularisation  
  - ejection fraction < 40%.  
  - acute heart failure (Killip IV) at the time of admission to the hospital  
  - dual antiplatelet therapy can not be maintained for 1 year after PCI  
  - haemorrhagic stroke in the past  
  - ischaemic stroke or transient ischaemia in previous 6 weeks  
  - platelet count < 100,000 / mm³  
  - chronic renal failure with creatinine clearance < 30mL / min / 1.73 m²  
  - planned surgery  
  - pregnancy or planned pregnancies  
  - expected life expectancy less than 3 years after enrolment |
| Interventions | **Intervention:** cardiac supervision and rehabilitation - optimal, continuous and regularly controlled tele-rehabilitation, based on exercise training, intensive dietary and educational program focused on lifestyle and risk factor modification.  
  **Comparator:** cardiac supervision |
| Outcomes | Mortality, cardiovascular events |
| Starting date | March 2018 |
| Contact information | Krzysztof Milewski; kpmilewski@gmail.com |
| Notes | }
**Study name**
Tele-CARDIAC Rehabilitation Program

**Methods**
RCT

**Participants**

**Inclusion criteria:**
- guideline-based and Israeli Health Basket approved indications for cardiac rehabilitation yet participant declines to participate in centre-based cardiac rehabilitation due to non-medical reasons such as: distance, service availability in participants' living area, time constraints and other logistic or sociocultural barriers;
- age ≥ 21 years;
- compatible smartphone (android or iOS) with internet connection;
- willing and able to comply with study protocol;
- able and willing to follow the personalised exercise prescription, use wearable technology and smartphone app, and upload data via personal smartphone.

**Exclusion criteria:**
- any unresolved cardiac condition associated with significantly increased risk during outpatient activity (clinically significant ischaemia, unresolved arrhythmia, high falling risk, etc.);
- end-stage/NYHA 4 or unstable heart failure (clinical) or unresolved significant arrhythmia (i.e. rapid atrial fibrillation);
- LVEF ≤ 35% without ICD/ CRTD;
- significant neurological or cognitive impairment or markedly unstable gait/high falling risk;
- women of child-bearing potential;
- ACS within 30 days prior to screening, or having undergone cardiac surgery within 30 days prior to screening;
- inability to perform a stress test due to physical limitations;
- severe angina pectoris as defined by Canadian Cardiovascular Society (CCS) Angina Score > 2;
- pulmonary disease of severity greater than mild (COPD, asthma, interstitial lung disease (ILD), connective tissue disease (CTD) with lung involvement) or chronic pulmonary thromboembolic disease (CTED);
- severe orthopedic limitations;
- active myocarditis, constrictive pericarditis, restrictive or hypertrophic cardiomyopathy;
- severe aortic or mitral stenosis;
- significant anaemia (Hb < 10 mg/dL);
- known drug or alcohol dependence or any other factors which will interfere with the study conduct or interpretation of the results, or in the opinion of the investigator, are not suitable to participate;
- any illness which reduces life expectancy to less than 1 year from screening.

**Interventions**

**Intervention:**
"The Tele-rehab arm will receive an exercise prescription and execution will be assessed and periodically adjusted in accordance to data received from the wearable device. Intensity and type of exercise will be moderate and will comply with exercise recommendations provided by ESC guidelines. A dedicated application will be installed on the mobile phone for patients in the research group and they will receive a smart sports watch." "Additionally, in the intervention arm, we will provide psychological support, dietary intervention and disease management services that complement the structured physical activity - all by innovative smartphone applications and smart wearable devices"

**Comparator:**
"The usual care arm will receive general recommendations for a healthy and active lifestyle and community cardiologist and primary care physician according to local guidelines."

**Outcomes**
hospitalisation, mortality, HRQoL
### NCT03584828

**Starting date:** July 2018

Dr. Robert Klempfner Heart Rehabilitation Institute, Head, Cardiovascular Prevention and Rehabilitation Institute, Sheba Medical Center, Israel, Sheba Medical Center

**Notes:**
NCT03584828 (Continued)

### NCT03905187

**Study name:** Stress Management Modified Cardiac Rehabilitation in Patients After Acute Myocardial Infarction or Heart Failure

**Methods:** RCT

**Participants**
- **Inclusion criteria:**
  Participants aged 18 to 80 years old with a diagnosis of AMI (include ST segment elevated myocardial infarction and non-ST segment elevated myocardial infarction) or heart failure.

- **Exclusion criteria:**
  Uncontrolled tachycardia (heart rate at rest > 120 bpm). Uncontrolled polypnoea (breath rate at rest > 30 breath per minute. Uncontrolled respiratory failure (SPO2 ≤ 90%). Uncontrolled hypertension (pre-exercise SBP > 180 mmHg or DBP > 110 mmHg). Weight change in 72 hours > 1.8kg. Uncontrolled hyperglycaemia (random blood glucose > 18 mmol/L). Uncontrolled malignant arrhythmia with haemodynamic instability. Unoperated pseudoaneurysm. Artery dissection. Unoperated septic shock and septicopyaemia. Unoperated severe valvular heart disease or acute phase of heart failure caused by myocardial heart disease. Nervous system disease, motor system diseases and rheumatic diseases considered possibly worsened by exercise. Uncooperation of the participants.

**Interventions**
- **Intervention 1:**
  Modified CR - cardiac rehabilitation including stress management, exercise and education.

- **Intervention 2:**
  Traditional CR - including education and exercise.

- **Comparator:**
  Education only (control group)

**Outcomes:**
HRQoL, rehospitalisation, MACE

**Starting date:** April 2019

**Contact information:**
crystalma@126.com

**Notes:**

### NCT03978130

**Study name:** Rehabilitation at Home Using Mobile Health in Older Adults after Hospitalization for Ischemic Heart Disease (RESILIENT)

**Methods:** Multicentre RCT

**Participants**
- **Inclusion criteria:**
NCT03978130 (Continued)

1. Age ≥ 65 years.
2. Currently hospitalised for AMI, PCI, or CABG, or hospitalised for AMI, PCI or CABG within prior 2 weeks.
4. Understands and is able to perform study procedures (i.e. 6-minute walk test, use mHealth software in English or Spanish).

**Exclusion criteria:**

1. Non-ambulatory.
2. Moderate or severe cognitive impairment.
3. Unable/unwilling to consent.
4. PCI-related groin hematoma that precludes brisk walking.
5. Incarcerated.
6. Unable to use mHealth software in English or Spanish.
7. Severe osteoarthritis, or joint replacement within last 3 months.
8. Parkinson’s disease or other progressive movement disorder.
9. Regular use of walker for ambulation.
10. Projected life expectancy < 3 months.
11. Clinical judgment concerning other safety or non-adherence issues.
12. Participants admitted from long-term care facility.
13. Currently listed for heart transplant.
14. Left ventricular assist device recipient.
15. Completion of ambulatory cardiac rehabilitation program within prior 3 months.

**Interventions**

**Intervention:**

mHealth-CR: participants receive 3 components for their home activity: (1) communication with exercise therapist (in-hospital assessment/counselling followed by regular communication post-discharge), (2) mHealth-CR software, and (3) wearable activity-monitoring device.

**Comparator:**

usual care

**Outcomes**

HRQoL, hospital readmissions, mortality

**Starting date**

January 2020

**Contact information**

resilient@nyulangone.org

**Notes**

NCT04425057

**Study name**

Effect of a High Intensity Interval Training in Older Adults With Coronary Artery Disease

**Methods**

RCT

**Participants**

**Inclusion criteria:**

- diagnosed with coronary artery disease
- discharged from hospital, less than 2 months

**Exclusion criteria:**

Exercise-based cardiac rehabilitation for coronary heart disease (Review)

Copyright © 2021 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Interventions

**Intervention:** physiotherapy program during two months: interval training at a high intensity, including a warm-up and a cool-down. Aerobic exercises, resistance exercises, stretching.

**Comparator:** no physiotherapy.

Outcomes

HRQoL (SF-36)

Starting date

October 2012

Contact information

Elena Marques-Sule, PhD, PT, University of Valencia

Notes

NCT04425057 (Continued)

• not able to move by themselves

NCT04438356

Study name

M-Health Care for Patients After AMI on Disease Perception, Self-Efficacy, Anxiety and Cardio-Respiratory Fitness

Methods

RCT (waiting-list control)

Participants

**Inclusion criteria:**

- Taiwanese, understand Chinese
- Participants who are over 20 years old and have AMI (including ST segment ascending and non-ST segment ascending), diagnosed by percutaneous coronary intervention and without complications within 30±5 days, the left ventricular injection rate is greater than 40%
- Ability and willingness to provide informed consent
- Have a smartphone
- Can receive and send smartphone messages

**Exclusion criteria:**

- Those who can’t express their wishes clearly (such as mental dysfunction)
- Mental disorder
- People who participate in other research projects
- Planned coronary artery bypass surgery or other diseases that require continuous heart care
- Abuse of alcohol or narcotics
- Left ventricular ejection fraction (LVEF) is less than 40%

Interventions

**Intervention:**

M-Health app to remind participants of the walking frequency and time, and use Garmin monitoring bracelet to record daily walking steps. App content also includes knowledge about acute myocardial infarction, self-care and anxiety.

**Control:**

Waiting-list control for 3 months, then receive the same M-Health intervention

Outcomes

Starting date

22 July 2020

**Notes**
An Internet-based Cardiac Rehabilitation Enhancement (i-CARE) Intervention to Support Self-care of Patients With Coronary Artery Disease

**Methods**

RCT

**participants**

**Inclusion criteria:**

- ≥ 18 years of age
- living in the community
- own a smartphone with internet access
- communicable in Cantonese
- type in Chinese or English
- with a confirmed diagnosis of CAD

**Exclusion criteria:**

- enrolled to a structured centre-based or home-based cardiac rehabilitation program
- psychiatric problems
- impaired cognitive functioning (i.e. Abbreviated Mental Test ≤ 6)
- terminal disease with life expectancy < 1 year

**Interventions**

**Intervention:**

participants in the intervention group will receive a 12-week i-CARE intervention, which will be designed to cover the core elements of CAD self-care: self-care maintenance, self-care monitoring and self-care management. The intervention will comprise: 1) a single individualised face-to-face session, and 2) an internet-based intervention through a mobile application. Various behaviour change techniques will be used to increase the self-efficacy of CAD patients in enacting self-care behaviours.

**Comparator:**

participants will receive conventional care as arranged by hospital or community centres.

**Outcomes**

cardiovascular events, mortality, HRQoL

**Starting date**

May 2021

**Contact information**

Dr. Polly Wai-Chi Li, The University of Hong Kong pwcli@hku.hk

**Notes**

NCT04858503

ACS: acute coronary syndrome
AMI: acute myocardial infarction
APVD: atherosclerotic peripheral vascular disease
CABG: coronary artery bypass graft
COPD: chronic obstructive pulmonary disease
CPET: cardiopulmonary exercise test
CRTD: cardiac resynchronization therapy defibrillator
CTED: chronic pulmonary thromboembolic disease
DBP: diastolic blood pressure
HDL: high-density lipoprotein
HRQoL: health-related quality of life
ICD: implantable cardioverter defibrillator
LDL: low-density lipoprotein
LV: left-ventricular
LVEF: left ventricular ejection fraction
MACCE: major adverse cardiac and cerebrovascular events
MACE: major adverse coronary event
NYHA: New York Heart Association

Exercise-based cardiac rehabilitation for coronary heart disease (Review)

EuroQol: European Quality of Life Scale
IQR: interquartile range
MIDAS: Myocardial Infarction Dimensional Assessment Scale
NR: not reported
NS: not significant
QLMI: Quality of Life After Myocardial Infarction questionnaire
SD: standard deviation
SF-36: Short Form 36-item questionnaire
WHOQoL-BREF: World Health Organization Quality of Life abbreviated instrument
* Calculated by authors of this report based on independent two group t test.
** Adjusted for baseline difference between groups.
Exercise = Control: no statistically significant difference (P > 0.05) between exercise and Control groups at follow up
Exercise > Control: statistically significant difference (P < 0.05) between exercise and Control groups at follow up
NS*: The authors of this review have inferred a P value of > 0.05 based either on the 95% CI, or from narrative in the paper, rather than from directly observing the P-value.

**APPENDICES**

Appendix 1. Glossary of terms used in this review

**Angina pectoris:** commonly known as angina, is the sensation of chest pain, pressure, or squeezing, often due to ischaemia of the heart muscle from obstruction or spasm of the coronary arteries.

**Angioplasty:** a treatment to expand a narrowed artery.

**Arrhythmia:** an abnormal heart rhythm.

**Atheroma:** the fatty material that can build up within the walls of your arteries.

**Atherosclerosis:** the build-up of fatty materials within the walls of your arteries, causing them to narrow.

**Cardiovascular:** to do with the heart and blood vessels.

**Coronary artery bypass surgery:** also known as coronary artery bypass graft (CABG) surgery, and colloquially as heart bypass or bypass surgery, is a surgical procedure to improve the blood supply to the heart.

**Coronary heart disease (CHD):** also known as coronary artery disease (CAD), ischaemic heart disease (IHD), or atherosclerotic heart disease, is a group of diseases that includes: stable angina, unstable angina, myocardial infarction and sudden coronary death. It is caused when the walls of your coronary arteries become narrowed by a gradual build-up of atheroma, allowing too little blood flow to the heart from the coronary arteries.

**Echocardiogram:** often referred to as a cardiac echo or simply an echo, is a sonogram of the heart. Echocardiography uses standard two-dimensional, three-dimensional, and Doppler ultrasound to create images of the heart.
**Electrocardiogram (ECG):** is a test that checks for problems with the electrical activity of your heart. An ECG shows the heart’s electrical activity as line tracings on paper. The spikes and dips in the tracings are called waves. The heart is a muscular pump made up of four chambers.

**Heart attack:** myocardial infarction (MI) or acute myocardial infarction (AMI), occurs when blood flow stops to a part of the heart, starving it of oxygen and causing damage to the heart muscle.

**Heart failure (HF):** often referred to as congestive heart failure (CHF), occurs when the heart is unable to pump sufficiently to maintain blood flow to meet the needs of your body.

**Heart rate:** The number of times your heart beats in a minute.

**Implantable cardioverter defibrillator (ICD):** a device implanted within your chest wall to monitor your heart’s rhythm. If there is a dangerous, abnormal rhythm, the ICD can treat it by giving your heart an electric shock.

**Intermittent claudication:** A cramp-like pain, mostly in your calf and leg muscles, which is caused by a lack of oxygen in the blood. It is often brought on by walking and relieved by rest.

**Ischaemia:** a restriction in blood supply to tissues, causing a shortage of the oxygen and glucose needed.

**Ischaemic heart disease (IHD):** see coronary heart disease (CHD).

**Myocardial infarction (MI) or acute myocardial infarction (AMI):** commonly known as a heart attack, occurs when blood flow stops to a part of the heart, causing damage to the heart muscle.

**Percutaneous coronary intervention (PCI):** commonly known as coronary angioplasty, is a non-surgical procedure used to treat the stenotic (narrowed) coronary arteries of the heart found in coronary heart disease.

**Revascularisation:** a procedure that either opens up the existing blood vessels or bypasses the blockage of the coronary arteries.

**Risk factor for coronary heart disease:** something that can increase your risk of getting coronary heart disease. Risk factors include smoking, high blood pressure, raised cholesterol, physical inactivity, obesity, diabetes, your sex, your ethnic background, your age and whether you have a family history of heart disease.

**ST segment:** is the flat, isoelectric section of the ECG trace, between the end of the S wave (the J point) and the beginning of the T wave.

### Date | Event | Description
---|---|---
24 February 2015 | Amended | Author (David Thompson) details updated
7 June 2011 | New citation required and conclusions have changed | The inclusion criteria have been revised for this update. Five out of the 35 formerly included studies (in the review) have therefore been excluded.

The conclusions have changed based on the analysis of 47 included studies and have focused more on the impact of exercise-based cardiac rehabilitation on clinical events and HRQL outcomes.

7 June 2011 | New search has been performed | The searches were updated and re-run in December 2009, identifying an additional 17 studies for inclusion. Forty-seven trials in total have been included.
1 November 2000 | New citation required and conclusions have changed | Substantive amendment

### Contributions of Authors
This review update was undertaken by GD, JF and RST; namely, study selection, data extraction and risk of bias assessment.
A-DZ provided clinical advice during the process of the update.
GD, JF and RST wrote the first draft of the review update, and all co-authors contributed to reviewing and editing drafts of the review update.
All authors approved the final manuscript.

### Declarations of Interest
GD declares no conflicts of interest.
JF declares no conflicts of interest.
NO declares work as Professor at the University of Wisconsin-Milwaukee, USA. NO also declares being an author of a study that is eligible for inclusion in the work (funding source: European Society of Cardiology & European Association of Preventive Cardiology).
KR declares no conflicts of interest.
DRT declares being an author of a study that is eligible for inclusion in the work.
A-DZ declares being an author of a study that is eligible for inclusion in the work.
RST declares no conflicts of interest.

### Sources of Support
**Internal sources**
- University of Glasgow, UK
  Support in form of salaries

**External sources**
- NIHR, UK

This project was supported by the NIHR via Cochrane Infrastructure funding to the Heart Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health and Social Care.
DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In addition to updating the searches, the primary outcome of hospitalisation has been split to include both all-cause and cardiovascular hospitalisations. Due to the increased availability of HRQoL outcome data in this update, we were able to undertake a formal meta-analysis of this outcome (based on a number of measures, including SF-36 summary and domain scores, EQ-5D scores, and total/overall HRQoL scores). An additional meta-regression study level category has been added (low- and middle-income versus high-income countries), to allow us to explore if effect sizes varied by these settings.

In previous versions of this review, three additional risk of bias domains were included (groups balanced at baseline, intention-to-treat analysis undertaken and groups received comparable treatment (except exercise)). For this review update, we decided that these additional domains were no longer applicable and removed them.
