ABSTRACT

Decentralization and the Productive Efficiency of Government: Evidence from Swiss Cantons*

Advocates of fiscal decentralization argue that amongst other benefits, it can increase the efficiency of delivery of government services. This paper is one of the first to evaluate this claim empirically by looking at the association between education expenditure decentralization and the productive efficiency of schools using a data-set of Swiss cantons. We first provide careful evidence that expenditure decentralization is a powerful proxy for legal local autonomy. Further panel regressions of Swiss cantons provide robust evidence that more decentralization is associated with higher educational attainment. We also show that these gains lead to no adverse effects across education types but that male students benefited more from educational decentralization closing, for the Swiss case, the gender education gap.

1. Introduction

Fiscal decentralization, the allocation of tax and spending powers to lower levels of government, is now an established policy objective, in many developed and developing countries. Moreover, it is actively promoted as a development strategy by organizations such as the World Bank (Azfar et al., 2001, World Bank, 2000). The usual advantages that are claimed for decentralization that one can find in the literature include the following (Azfar et al., 2001, Lockwood, 2005, Oates, 1999). First, decentralization is claimed to improve *allocative efficiency*, in the sense that the goods provided by governments in localities will be better matched to the preferences of the residents of those localities. This is sometimes known as the *preference-matching* argument. Second, decentralization is argued to increase the *efficiency* of delivery of government services. In this literature, production efficiency is interpreted in a wide sense, to accommodate inefficiencies like corruption, waste, and poor governance. There is now quite a large literature on decentralization and allocative efficiency¹. By contrast, the literature on decentralization and productive inefficiency is small.

The theoretical literature identifies three mechanisms by which decentralization may lead to increased efficiency². The first is that decentralization may give voters increased electoral control over incumbents. For example, in Seabright (1996) and Persson and Tabellini (2000, Chapter 9), decentralization is shown, under some conditions, to reduce the incentives for incumbents to divert rents from tax revenue, because under decentralization, the (negative) link between such rent diversion and the probability of re-election is stronger. Hindriks and Lockwood (2005) extend this argument to show how decentralization may increase the equilibrium probability that corrupt incumbents are voted out of office (a stronger *selection effect* in the terminology of Besley and Smart, 2004).

The second mechanism is that decentralization enables yardstick competition between sub-national governments: voters can use the performance of neighbouring governments (or governments of regions that are otherwise similar to their own) to make inferences about the competence or benevolence of their own local politicians (Besley and

¹See for example, Alesina and Spolare(1997), Besley and Coate (2003), Bolton and Roland (1997), Ellingsen (1998), Gilbert and Picard (1996), Lockwood (2002), Oates (1972), Oberholzer-Gee and Strumpf (2002), Wallis and Oates(1988).

²Note that along with all of the related literature, we estimate a reduced form relationship between fiscal decentralization and productive efficiency. In our data set, we have no way of distinguishing between the lobbying channel, and the political agency channel. In particular, data on any dimension of lobbying activity in any country, including Switzerland, is very hard to find, and does not exist at the cantonal level.

Smart(2004), Bordignon, Cerniglia, and Revelli (2004))

The third mechanism is that decentralization may lead to a decrease in lobbying by interest groups, which both distorts policy choice and increases waste of public funds. Here, a small number of contributions by Bardhan and Mookherjee (2003), Bordignon, Colombo, and Galmarini (2003), and Redoano (2003) emphasize that the link between decentralization and lobbying is ambiguous. Indeed, under some conditions, there can be more lobbying and distortion of policy choice under decentralization, confirming the belief, going back to the US Federalist Papers in the 18th century, that local government is more susceptible to “capture” by lobbies.

The existing empirical literature does not try to precisely identify these mechanisms. Rather, the approach is to look at a reduced-form relationship between fiscal decentralization and some indicator of the efficiency of government. This literature is, to our knowledge, principally based on cross-country data. The level of fiscal decentralization is usually³ measured by the percentage of government expenditures made, or taxes collected, at sub-national level, as recorded by the IMF’s Government Financial Statistics. These papers then run regressions where the dependent variable is some easily measured and internationally comparable outcome of government activity against the preferred decentralization measure together with a set of controls. For example, in Khaleghian, 2003, the outcome is immunization coverage rate in the population Treisman, 2002, used immunization coverage also, along with basic drug availability, youth illiteracy rates, and the number of kilometers of paved road per resident of the country. Alternatively, some papers use as the dependent variable some more general indicator of government effectiveness (Huther and Shah, 1998), or corruption (Mello and Barenstein, 2001, Fisman and Gatti, 2000).

In our view, there are two main problems with this literature. First, many of these papers rely on the IMF measure of fiscal decentralization which - it is widely recognized - does not measure very accurately the true autonomy of sub-central government to choose expenditures and set taxes⁴. Second, these regressions do not estimate government “pro-

³Triesman (2002) is an exception here: he uses several different constitutional indicators of decentralization, such as a dummy variable for a federal country, the number of different tiers of government, etc.

⁴For a critique of the IMF’s Government Finance Statistics. the use of these statistics as measures of the true autonomy of local governments, see Ebel and Yimaz(2002). These statistics tend to overestimate the share of government expenditure and tax revenues that are under the control of sub-national government, and they do so in a way that varies widely across countries. For example, consider a country (e.g. Germany) where some taxes are set nationally but where the revenues are shared with sub-national governments via a fixed formula. The share of tax revenue going to sub-national government is measured

duction functions”, because they do not control for the *inputs* to the output that is the dependent variable. For example, several papers that study health outputs do not control for health expenditures, number of doctors, etc. In the absence of controls for these inputs, these regressions can not tell us much about the efficiency of government as any observed correlation between decentralization and government output can be attributed to omitted variable bias.⁵

To confront these criticisms, our paper uses data on fiscal decentralization and educational inputs and outputs from Swiss cantons over the period 1982-2000. There are several advantages of these data. First, there are data on the level of fiscal decentralization of spending on education within each Canton, collected on a consistent basis over Cantons and years. So, this indicator is likely to be a much better indicator of true fiscal autonomy than in the cross-country case. Moreover, the spending relates to education only, and so there is no danger of the kind of aggregation bias that arises when using the decentralization of *total* expenditure as an indicator, as do the studies cited above. Our paper also relies on specific features of the Swiss context that allow us to treat the variation in decentralization to be exogenous with respect to educational attainment, discussed further in Section 2.4 below.

As an additional check on this, we study the relationship across Cantons between the spending measure of decentralization and various direct measures of sub-cantonal autonomy in educational policy, specifically, which level of government has the authority to appoint teachers and/or determine their pay level, whether the local government has the power to set incentive pay, and whether they have some powers over the organization of the school or curriculum. There is a strong positive correlation between the expenditure measure and an index of these direct measures. Second, in contrast to the existing literature, as well as measuring “output,” we can control for the influence of inputs on educational outputs, such as educational expenditure per pupil and class size. In our sample the education output in a given year is the fraction of the 19 year old population that obtains the Maturité certificate that allows continuation to university.⁶

in the IMF’s statistics as sub-national revenue, even though the lower level of government may have little or no control over choice of the rate or the base. Similar problems appear on the expenditure size from spending that is mandated by central government but implemented by lower-level governments.

⁵For example, if it is found that decentralization is positively related to immunization rates (as does Khaleghian, 2003), this could simply reflect the fact that decentralized countries spend more on immunization, not that they can deliver this service with greater efficiency.

⁶This measure is a natural choice for Switzerland as standardized test scores are not available. Other papers (Jacob and Lefgren, 2005), employs measures of educational attainment combined with subjective teacher performance evaluations. Using US data they show that higher poverty schools strongly value

Our main finding is that there is a robust positive relationship between fiscal decentralization and productive efficiency of public good provision in the case of education. This is present even when canton and year effects and further control variables are allowed for. Finally we find no empirical support that the gains were accompanied by losses in terms of other measures of educational attainment. However, we should note that because the education “production function” is being estimated at the level of the canton, rather than the individual school, our finding might be interpreted as partly due to better preference-matching with fiscal decentralization. For example, more decentralized cantons may be better able to direct resources towards schools where they know there is a stronger demand for education up to maturité level.

We also take our investigation further by asking whether other - possibly time-invariant - features of cantonal and local government interact with decentralization of education to affect the Maturité pass rate. We find that a five-year moving average of both cantonal and local budgetary surplus (which we take to measure “good governance”, following Galiani. and Schargrodsky, 2002) tends to have a positive interaction effect on the pass rate. So, a given amount of decentralization will lead to greater efficiency gains if the local government is more competent.

We also find, that the number of local jurisdictions in a canton (which we take to measure possible economies of scale) has a negative interaction effect on decentralization. This is consistent with theoretical predictions, centralizing expenditure on education will have greater efficiency gains - or rather, smaller losses - when the scope for economies of scale is larger.

The rest of the paper is laid out as follows. Section 2 describes the context of decentralization in Switzerland and why the variation in decentralization can arguably taken to be exogenous. Section 3 assesses the extent of local autonomy across cantons and its relationship to expenditure decentralization. Section 4 then turns to the empirical evidence of expenditure decentralization and educational attainment. Section 5 concludes and discusses the results.

student achievement and are essentially indifferent to the principal’s report of a teacher’s ability to promote student satisfaction.

2. Education Decentralization in Switzerland

2.1. Some Background

Switzerland is a Confederation of 26 cantons. These cantons are independent from the federal government in terms of school-level education and most aspects of the day-to-day life in which the state is involved. These 26 Cantons are further divided into 2896 local counties. Table 1 gives for each canton the number of local counties, the average population size per county and the average surface per local county.⁷ As it is apparent, the number of local counties per canton, also referred to as fragmentation, is associated with population size. A simple correlation between population size in a canton and the number of local counties is 0.69, so more populous cantons have more local counties. Despite this high correlation between population size and the number of counties there is still a large variation in the degree of *administrative decentralization*, as measured by the average population per local county in a canton. As the number of counties per region does not vary over time we control for this aspect of administrative decentralization by fixed effects.

Our focus is on school education. In Switzerland, there is a primary school level, a lower secondary school level, and, finally, an upper secondary school level. The first two school levels comprise the nine years of compulsory education⁸. The third level, with a duration of four to five years, offers the university entry qualification, called the Maturité, to students who successfully completed this school and past the final exams.⁹ This last level of education will be used as a proxy for educational attainment.

Many responsibilities are common across all cantons in the way they are shared between the local and the central government. Common features among all cantons are that the primary school is the exclusive responsibility of the local communities and many aspects of the upper secondary school is under the jurisdiction of the cantonal government. School material and the definition of aims, scope, and structure of school at all three levels are regulated by cantonal, i.e. central, law. Organizational issues concerning the day-to-day running of the schools like the allocation of pupils to classes, the enforcement of discipline at the school, and ensuring that pupils attend class are the responsibility

⁷The average surface is based on the total polygonal surface for each canton minus the non-productive surfaces, i.e. lakes, glaciers, rocks, etc.

⁸Many cantons however give pupils the option to stay on for one more year after the ninth year without giving an additional qualification.

⁹There also exist professional schools that qualify students for field-specific tertiary education. We return to those type of schools in the section assessing adverse effects of decentralization.

Table 1: Descriptive Statistics by Canton

Notes: Decentralization is defined as the ratio between the sum of all local expenditure in a canton and the sum of all local plus cantonal expenditures. ¹Based on total surface per canton minus non-productive surface (lakes, rock, glaciers). The population data is based on an average between 1997 and 2001. ²Calculated for average education expenditure between 1981 and 1999. ³Average decentralization rate for 1982 to 1999 defined as the sum of all local expenditures across cantons on public education as a share of all expenditure by local and cantonal governments across cantons. The unweighted average across cantons is 0.61.

of the local counties. As in most OECD countries pupils are guaranteed a place in a school within the ‘catchment area’ of residence.¹⁰ Furthermore pupils can only attend schools of another area under exceptional circumstances. Education is free for residents of a canton but school fees can be levied for pupils residing outside the canton; 95% of pupils in Switzerland attend public schools.

So as such pupils and parents only have a choice of school via the choice of residence. However unlike the US and the UK where the relative performance of schools across and within areas is well documented and made public, no generalized information of this kind exists in Switzerland. Even if parents get informed through casual observations and experience, no objective evaluation is available which suggests that school quality is not of first order importance in residential choice. We return to this point in more detail below.

Inspections and auditing of schools is present in all cantonal legislation and is made operational through external inspectors appointed by the central cantonal government.¹¹ They are in charge of training and evaluation of teachers, the supervision of school management, the observation of school curricula, and the use of teaching material, and the inspection of school locations.

2.2. Decentralization in Education Expenditures

As noted above, in Switzerland, responsibility for school-level education divided between the cantons and the local counties, with the federal government playing no role. Thus, a natural measure of decentralization is the degree at which local counties are in charge of public expenditure. We use data from the Swiss Federal Statistical Office. Our measure of expenditure decentralization in year t and in canton c , D_{ct} is

$$D_{ct} = \frac{LE_{ct}}{LE_{ct} + CE_{ct}} \quad (2.1)$$

where LE_{ct} is the sum of education expenditures in all counties in canton c in year t , and CE_{ct} is the sum of education expenditures at the cantonal level in year t . When all

¹⁰See for instance in Appenzell-Ausserrhoden art. 20 Schulgesetz, par 1. (Also in art 20.3 states that when pupils from another local county attend school than financial support can be requested from that county to help in the financing of those pupils; in Bern art. 7, Volksschulverordnung (VSV) 432.211; in Freiburg art. 8, Schulgesetz and also "Gesetz über den Mittelschulunterricht"; in Nidwald art. 11 Volksschulgesetz (312.1); in St. Gallen art.s 52 and 53 Volksschulgesetz; in Solothurn art. 45, Volksschulgesetz, or in Schwytz art. 32 Verordnung über die Volksschulen.

¹¹For instance see the legislations of the cantons of Thurgau (art 5, 410.1 Unterrichtsgesetz, www.tg.ch), Valais (Titre 2, Chapitre 1, 400.1 Loi sur l’instruction publique, www.vs.ch), or Zug (art 67, 411.11 Schulgesetz, www.zg.ch)

expenditures are carried out on the local level $D_{ct} = 1$, and when the cantonal government is solely in charge of expenditure then $D_{ct} = 0$.¹²

For the education sector we see in Table 1 that the average level of D_{ct} in Switzerland is 0.55, that is about half of all expenditure on primary and secondary education in a canton is spent by the local counties. Whereas Basel-City is a very centralized canton along this measure, Obwald is almost entirely decentralized. The last column in Table 1 gives the standard deviation of education decentralization for each canton which reflects the variation in decentralization within a canton over time. Two facts can thus be highlighted. First there is sufficient time variation of D_{ct} within each canton for meaningful fixed effects regressions. Second, there is no general discernible time trend in decentralization.

A key question, of course, is what D_{ct} is really measuring. First, in the empirical literature on fiscal decentralization, there is always a concern that fiscal indicators may not measure the true autonomy of sub-central government over educational policy decisions. (Ebel and Yimaz(2002)). In the next section, we address this issue in some detail.

2.3. Decentralization and Autonomy

The purpose of this section is to see how actual legislation on local autonomy is related to observed decentralization. As the primary school is always under local and the upper secondary always under central jurisdiction we focus on the delegation of decisions at the lower secondary school. Specifically we identified who is in charge of:

- appointing teachers,
- determining the pay level of teachers,
- teachers' incentives
- structural school organization.

In each of these four aspects of education policy, we made a judgement, based on our reading of legal sources, as to whether the policy was wholly under the control of central (cantonal) government or local government. Table A2 describes in detail the legal sources, and the level of government responsible for each of the four decisions, for each of the 26

¹²An issue that is raised in the literature on federalism is the transfers across states via the federal government - or in our context between the cantonal governments and the local counties. In Switzerland, the local counties principally raise their own taxes to cover expenses and the transfers play, in general, a minor role in adjusting living standards across regions.

cantons. The sources relate to current legislation as of August 2003. Where possible each legislations has been traced back to assess if within the sample period there have been changes to these laws; but no evidence for such changes have been found.

To interpret this table, it is probably helpful to go into more detail on the last three dimensions of autonomy. The second dimension asks whether pay can be set at the local level. In most cantons, teachers' pay is regulated by the law on civil servants. Each teacher is allocated a pay grade (or spinal point) depending on qualification, the type of occupation, and work experience. However in a few cantons the local counties can make additional payments to attract teachers or can independently design their own pay systems.

The third dimension of local autonomy concerns the presence of incentive pay set at the local level. Usually teachers, after being hired, are automatically promoted at the beginning of each academic year to the next pay grade (or spinal point). However in some cantons¹³, this progression can be put to a halt should the performance of teachers be insufficient. Then teachers can either be kept on the same pay level or even relegated to a step further down the salary scale.

The fourth dimension concerns local autonomy in terms of school organization. This does not refer to routine management of schools, but whether local counties can in fact make important *structural decisions* of some kind. Here we find that four cantons can indeed make such choices. In two cantons the local counties can choose between different school models to provide a specific level of education (Appenzell-Ausserrhoden and Zürich). In a further two cantons - Solothurn and Valais - local counties can decide whether they want to introduce an additional 10th year of education.¹⁴ Finally, the canton of Valais entitles the local counties to decide if they want to regroup pupils from different school years for reasons of effectiveness.

¹³This form of autonomy is present in the cantons of Appenzell-Ausserrhoden, Glarus, Nidwalden, Zug and Zurich and to a certain extent (punishment requested by local authority and granted by cantonal government) in Basel-Landschaft. In the canton of St. Gallen teachers can be dismissed by the local counties. Apart from such "sticks," some cantons allow the local counties to award its teachers "carrots" in the form of performance related pay. This can take on different forms. In Appenzell-Ausserrhoden, local governments can spend up to 0.2% of their wage bill on performance related pay. In Schwytz local councils can budget a specific credit - referred to as *Spontanhonorierung* (spontaneous reward) - of up to 0.3% of gross total wage pay. If this credit is granted by the local legislative body, school councils can then reward teachers for their exceptional performance. In Zug, local councils are generally also allowed to make such bonus payments.

¹⁴Except for these two cantons the presence of the 10th year is regulated by cantonal law and local counties can not choose to introduce when it is not present or opt out of it when it is.

In Table 2 cantons are ranked in descending order in terms of their level of education decentralization defined as the sum of local expenditures divided by all education expenditure, local and central, in a canton. In columns (3) to (6) we show if a canton allows for local autonomy in any of the four types of dimension discussed above. This table reveals an interesting pattern: cantons with high levels of decentralization are more likely to have broader local autonomy. In particular one can see that cantons with more decentralization have a higher probability to give their local counties autonomy over teachers' incentive pay. A simple cross section regression analysis - not reported - makes this point more formally where we regress the average level of decentralization per canton over time on a set of dummy variables equal to one if in a local autonomy is present. Two categories have statistically significant explanatory power: autonomy over teacher appointment and on teacher incentive pay is positively correlated with higher decentralization and over 70% of the variation in decentralization across cantons can be explained by a variation in autonomy.¹⁵

We can thus conclude that autonomy is indeed associated with to expenditure decentralization in this specific context. The question then arises as to why we do not use the four autonomy measures (or some index based on them) directly in regressions below explaining the maturité rate. The answer is simply that the autonomy measures are not time variant and therefore their effects are indistinguishable from canton fixed effects. So, in our regressions below, the effect of fiscal decentralization on the maturité rate is identified from the time-series variation in D_{ct} . So, it is important to know that this variation is not just random noise. We now turn to discuss this issue.

2.4. Sources of Variation in Education Decentralization over Time

In this section, we argue that at least part of the time-series variation in D_{ct} can be explained by variations in school student numbers over time in a canton, and also that variation in student numbers is likely to be independent of the maturité rate.

Note first that the local and cantonal components of school education spending can be written by definition as:

$$\sum_l LE_{lct} \equiv \sigma LTS_{ct} + LOC_{ct}, \quad CE_{ct} \equiv (1 - \sigma_c) LTS_{ct} + HTS_{ct} + COC_{ct} \quad (2.2)$$

where LTS_{ct} denotes the total teachers' salary bill in primary and lower secondary edu-

¹⁵This result is also robust to the introduction of other control variables: cantons that are more fragmented in the administrative divisions - as measured by the population per local county - do have higher decentralization.

Table 2: Sources of Variation in Education Decentralization

	(1)	(2a)	(2b)	(2c)	(3)	(4)	(5)	(6)

Note: Education decentralization is defined as the sum of all local expenditure divided by cantonal expenditure plus the sum of all local expenditure in a canton. Local share of teacher costs refers to the share of teacher salaries and compensations that are financed at the local level. The correlation between the degree of decentralization and the cost share is 0.81. Legal sources on cost shares are available upon request. In column 2b we report the marginal effect of changes in student numbers in a canton on the level of decentralization. In 15 out of 26 cantons the effect significant and in 13 cantons the coefficient is of the expected sign. An 'x' denotes that a decision is taken at the local rather than at the central level; (x) decision is shared between local and central government. Teacher Incentives refers to decisions about performance related pay (pay level increment, bonus etc.); School Organization refers to decisions about significant organizational matters (class structure, schemes). See Appendix 1 and 2 for definitions and legal sources on autonomy.

cation (lower-school) in canton c at time t , HTS denotes the total teachers' salary bill in higher secondary education (higher-school) in canton c at time t , and finally LOC_{ct}, COC_{ct} denote other education costs incurred at local and cantonal level which may be a function of the number of students.

These formulae describe several important stylized facts of the Swiss context. First, in all cantons, the cost of teachers' salaries at the lower level are shared between local counties and the canton. In particular, the share σ_c varies across cantons but is fixed over time during our sample period¹⁶: it is given for all cantons in column (2a) of Table 2. Note that there is quite a lot of cross-section variation in σ_c : for example, in the canton Obwald the full cost of teacher salaries is financed at the local level, whereas in Zürich 67% of the cost is borne by the local counties and finally in Geneva all costs are covered by the central government. Second, the cost of cost of teachers' salaries at the higher secondary level is paid entirely by cantonal government. Third, all other costs are shared between local and cantonal government. We do not have details on the sharing of other costs, but we do know that other costs in the aggregate are relatively unimportant compared to teachers' salaries - the latter comprise 50-70% of spending in the aggregate (Plotke, 1979, 2003)

Note that (2.1) and (2.2) must explain fully the variation over time in the decentralization indicator, in particular,

$$D_{ct} \equiv \frac{\sigma_c LTS_{ct} + LOC_{ct}}{LTS_{ct} + HTS_{ct} + LOC_{ct} + COC_{ct}} \quad (2.3)$$

This shows that mathematically, variation over time in the indicator must come from either (i) fluctuation in lower-school teacher salaries LTS_{ct} ; (ii) fluctuation in local and central other costs, and (iii) cantonal expenditure on higher-school teacher salaries and other costs which may be related to the number of students.

Moreover, as the cost of lower-school teacher salaries is shared between the central and the local governments in a fixed ratio, a change in the number of teachers in a canton generically induces a change in the degree of decentralization. Indeed when the local cost share σ_c in a canton is higher (lower) than the degree of decentralization, $\sigma > D_{ct}$, then more teachers leads to a subsequent increase (decrease) in the level of decentralization¹⁷.

¹⁶These local shares do not vary over time for the sample period. Legal sources for this data are available from the authors.

¹⁷For example in the canton of Fribourg where on average the degree of decentralization is 0.50 and the local cost share is 0.65 an increase in the number of teachers leads on average to an increase in decentralization whereas in Zug, where decentralization is at 0.74 and the local cost share is 0.50, more teachers leads to lower decentralization.

Mathematically, from (2.3):

$$\frac{\partial D_{ct}}{\partial LTS_{ct}} = \frac{\sigma - D_{ct}}{LTS_{ct} + HTS_{ct} + LOC_{ct} + COC_{ct}}$$

Thus the foremost source of year-to-year variation of decentralization in a canton is induced by changes in the number of teaching personnel and their compensations.

Second, all cantons regulate the class sizes for all school levels by imposing minimum and maximum class sizes.¹⁸ When a class in a school goes above or below these thresholds readjustments are made either by relocating students to other classes within the same school or across nearby schools. So, ultimately changes in student numbers in a canton will lead to straightforwardly changes in teacher salary costs (though cantons have the discretion to adjust to changes in student numbers¹⁹ by hiring more part-time teachers or not renewing their contracts, or hiring new full-time permanent teachers). Thus, in principle, an important source of variation in the variable LTS_{ct} over time is variation in the size of the student population in canton c over time.

This shows up in our data. We can also establish empirically that there is a positive relationship between student numbers and the level of decentralization in those cantons where the local cost shares in teacher salaries is higher than the level of decentralization. As the level of expenditures on education other than salaries varies across cantons the effect of changes in student numbers on the level of decentralization will vary, too. Furthermore changes in student numbers may entail other expenditures that are financed by the local or the cantonal governments depending on each canton. As we do not disaggregated data decompose expenditure types within the education category we follow a more general approach by estimating;

$$D_{ct} = \sum_c \theta_c F_c + \sum_c \kappa_c (F_c \times S_{ct}) + \xi_{ct} \quad (2.4)$$

where F_c are canton dummies which model fixed effects in the level of decentralization and S_{ct} are the student numbers in a canton and year which is interacted with the canton fixed effects F_c . As no intercept is present in this model, the κ_c measure the effect of changes in the number of students separately for each canton. The prediction is that the coefficient κ_c is positive (negative) when the local cost shares are higher (lower) than the level of decentralization. We estimated this model and report the κ_c coefficients in column (2b) of Table 2.

¹⁸For reasons of space the legal sources have been omitted but are available upon request.

¹⁹It can be argued that schools have differential incentives to exhaust the possibilities of adjusting classes through relocating students rather than by hiring more teachers if they have to face more of the financial burden themselves when the cost shares are high. We return to this point in section 4.6.

As can be seen the coefficient has the predicted sign in 13 cantons, in 11 cantons the coefficient is insignificant and but in 2 cantons is the coefficient of the opposite sign than predicted. Thus we find broad empirical support that changes in student numbers induce changes in the level of decentralization.

The question then arises as to whether over time, changes in student numbers in a canton over have any additional power in explaining the maturité rate, over and above their effect on D_{ct} . This is investigated in the next section, where we study the determinants of the maturité rate. Column 7 of Table 3 below shows that for our preferred specification, which obviously includes the variable D_{ct} , student numbers has no significant effect on the maturité rate. This insignificance seems to be quite robust across a number of different specifications (details on request).

This finding is also consistent with the fact that in Switzerland - in contrast to the U.K. or the U.S.A. - there is no school level or even canton level ranking of schools that are made available to students, parents, or teachers which would allow them to update over time their information about school quality. Thus parents, for instance, do not have yearly updates on school performance on which they can base their decision where to move to enrol their children²⁰. So, we would not expect student numbers to vary directly with the maturité rate.

3. Decentralization and Educational Attainment

3.1. Empirical Strategy and Data

We now turn to an econometric estimation of the relationship between decentralization and efficiency of public good provision in the educational sector. We will approach the estimation with a panel data set of 26 Swiss Cantons over the period 1982-2000. We have for each canton yearly observations on fiscal decentralization D_{ct} , a measure of educational output, the maturité rate E_{ct} , and various input measures. All these variables are defined in Table A1 and are discussed in more detail below.

We estimate the effect of decentralization in canton c in year t , on the educational attainment E_{ct} with

$$E_{ct} = \alpha_c + \beta_t + \gamma D_{ct}^{t-1,t-k} + \eta X_{ct}^{t-1,t-k} + u_{ct}. \quad (3.1)$$

²⁰There may well be time-invariant differences across schools due to historic differences in the level of development across cantons which parents are aware of. Yet, these permanent differences are controlled for by fixed-effects.

All variables are converted into natural logarithms. The variable $D_{ct}^{t-1,t-k}$ contains a measure of the degree of decentralization that affected a cohort in period t in canton c over the past k periods. This allows to capture the effect a cohort of students experienced over their whole schooling career. Specifically in the regression we will model $D_{ct}^{t-1,t-k}$ by

$$D_{ct}^{t-1,t-k} = \frac{D_{ct-1} + \dots + D_{ct-k}}{k}, \quad (3.2)$$

i.e. as a moving average of the past k periods.²¹ The next section will vary k to filter out the appropriate specification. In particular we will identify separately the effect during the whole schooling career, i.e. during the past 12 years, and separately from the effect during the post-compulsory upper-secondary education, i.e. during the past 5 years, and during the primary and lower secondary education period, i.e. during the first seven years of education.

Similarly the vector $X_{ct}^{t-1,t-k}$ contains moving averages of the past k periods of further control variables capturing the quality of the human resources, schooling infrastructure, and per student expenditure. Finally α_c are canton and β_t are year fixed effects and u_{ct} are unobservable disturbance terms clustered at the cantonal level. The precise specification of u_{ct} will be explained and discussed below.

So, (3.1) can be interpreted as a canton-level production function relating educational "output" E_{ct} to "inputs" $X_{ct}^{t-1,t-k}$ and the decentralization indicator (3.2). So a positive sign for coefficient γ indicates that increased fiscal decentralization leads to greater "output" for given "inputs" i.e. implies greater productive efficiency.

The main²² output variable E_{ct} is the *Maturité rate* which is the number of students who obtain the university entrance level qualification deflated by the size of the 19 year old population. Overall in Switzerland in 2000 17% of the 19 year old population obtained the *Maturité* which entitles them to attend university. This level of education is four to five years beyond the compulsory level of education in Switzerland. Numerous studies have shown how students who obtain this level of education have higher future income, better choice of jobs and subjective well-being.

Turning to choice of input variables, there is a vast literature on the economics of education that concentrates on the question as to which input measures affect educational attainment (Hanushek, 1997 and 2003). Our choice of variables is constrained by data

²¹We also allowed discounting values further in the past which yield similar results.

²²However, not all students who continue their education at the upper secondary school level, i.e. beyond compulsory education, attend schools that provide the *Maturité*, but rather attend *professional schools* that also lasts four to five years past compulsory schooling. In the next section we will also address the effect of decentralization on *professional school degrees*.

availability but includes such standard variables such as class size and expenditure per student at primary and secondary school level excluding tertiary education. To capture the effect of the social composition of the student population we have the proportion of students whose first language is different to the language of instruction: on average 16% of students are not instructed in their first language. By this we want to control for the fact that more foreign students can reduce the educational attainment of a cohort as they may be more difficult to teach due to the language barrier; in a way we thereby capture the quality of the input factor.

Of course, many other covariates contribute to the level of educational attainment of a specific individual student, such as neighborhood characteristics. However the focus of this paper is to identify the effect of the level of decentralization, which is measured at the cantonal level, and as such the identification and the bias of that coefficient is not sensitive to the omission of individual level data (Hoxby (2000)).

3.2. Regression Results

Table 3 turns to a set of panel regressions. In the first column we report a first cut at the data regressing the educational attainment among the 19 year old population in a year as a function of decentralization during the past 12 years, i.e. the average effect of exposure to variations in decentralization during the time this cohort spent in school. This regression is thus in the spirit of cross section regressions that ignore the problem of omitted variable bias induced by unobserved heterogeneity (Bardhan 2002). There is a significant *negative* correlation between decentralization and educational attainment. However this can be due to omitted factors that are specific to a region. The importance of this omitted variable bias is revealed when we add canton and year fixed effects in column (2). Note that now the coefficient is significantly *positive* at the 10% level. This illustrates that it is not innocuous to ignore the potential for unobserved heterogeneity stemming from historical or cultural differences that are correlated with the degree of decentralization. This can explain why in some studies using cross-section regressions a negative correlation has been found.

In column (3) we introduce our set of control variables. Per pupil expenditure, class size,²³ and the share of non-native speakers are not related to educational attainment. The coefficient on educational expenditure has the expected positive sign just as larger classes are related to lower educational attainment. When we omit the least significant

²³This refers to total expenditure, local and central, per pupil. Equally, class size refers to cantonal yearly averages. Note that the effect is estimated only by the variation within a canton over time.

Table 3 – Decentralization and Educational Attainment in Swiss Cantons

Adjusted R-squared	0.4480	0.9516	0.9539	0.9536	0.9544	0.9544	0.9543
Number of observations	208	208	208	208	208	208	208

Notes: * significant at 10% level, ** at 5% level, *** at 1% level. See Table A1 for definition of variables. Right hand side variables in column (1)-(4) are average values of past 12 years. In column 5 decentralization is split into average of past 5 years - proxying for the period during upper secondary school - and 6 to 12 years in the past - proxying for the period during primary and lower secondary school. In column (6) we measure business cycles as the *cyclical* part of canton-level GDP per capita using the Hodrick-Prescott (1997) filter with $\lambda=1600$. Results in column (4) and (5) are robust to using the raw budget data instead of the smoothed data.

variables, class size and foreign language speakers, we find that expenditure per student is significant at the 10% level. Most notably however is that even after controlling for this last set of variables we find that decentralization is positively related to educational attainment.

So far the right hand side variables are the moving averages of the past 12 years, i.e. $D_{ct}^{t-1,t-12}$ and $X_{ct}^{t-1,t-12}$. In column (5) we identify separately the effect of changes in decentralization during the last 5 years of schooling, i.e. during the post-compulsory education at the upper secondary school, from the effect of changes during the first seven years of schooling;

$$E_{ct} = \alpha_c + \beta_t + \gamma_1 D_{ct}^{t-1,t-5} + \gamma_2 D_{ct}^{t-6,t-12} + \eta X_{ct}^{t-1,t-12} + u_{ct}. \quad (3.3)$$

We find that it is in fact the changes in decentralization experienced during the last five years of education that matter. The coefficient γ_1 is significant at the 5% level but γ_2 is not significant. The coefficient on expenditure per student remains significant at the 5% level.

Looking at column (5) of Table 3, our preferred specification, we see that if decentralization increased by ten percentage points it leads to a 4% higher share of 19 year olds obtaining the Maturité. This effect is quite large given that a one standard deviation increase in expenditure is only associated with 12% of a standard deviation increase in educational attainment.²⁴ A further concern are local business cycles which could drive educational attainment directly thus making our estimates of γ_1 biased. We thus constructed a measure of the local business cycle by taking the cyclical component of per capita GDP per capita using the using the Hodrick and Prescott (1997) filter. As can be seen in column (6) of Table 3 the coefficient of decentralization is robust and the coefficient on our business cycle measure is not significant.

3.3. Economies of Scale

It has often been argued that one crucial advantage of centralized provision of public goods is that it can benefit from economies of scale in the production process of public goods: it may be more efficient to focus the design, implementation, and maintenance of public goods in one place rather than have several jurisdictions simultaneously engage in the same production process. To assess if this claim holds in our context we proxy for the scope for economies of scale in two ways.

²⁴Calculated as $(0.0994 * 0.1805)/0.151 = 0.1188$

First we by look at the number of jurisdictions in a canton.²⁵ We thus estimate the following model:

$$E_{ct} = \alpha_c + \beta_t + \gamma D_{ct}^{t-1,t-5} + \rho(D_{ct}^{t-1,t-5} \times J_c) + \eta X_{ct}^{t-1,t-12} + u_{ct}. \quad (3.4)$$

The variable J_c measures the number of jurisdictions in a canton. Note that even though the number of jurisdictions is time-invariant, the interaction term is identified by the time-series variation in D_{ct} . The idea of estimating the interaction term is to capture scale economies that are not a function of population size but only driven by the number of administrations in a canton. This is arguably a plausible measure of economies of scale as an important part of administration takes place at the school level whose size is determined by local factors and is difficult to vary. The empirical prediction is that the interaction term is negative, i.e. $\rho < 0$: decentralizing is more efficient when there are fewer jurisdictions involved in the process. Among the Swiss cantons the number of jurisdictions varies considerable between 3 in Basel-Stadt and 400 in Bern. In Table 4 column (1) we report results using the same sample as in Table 3. We restrict the specification to those variables that were significant in Table 4, column (5). As can be seen the coefficient on the interaction term is negative and significant at the 5% level. The coefficient on decentralization γ_1 now increases to 0.6. This is mainly due to the presence of the interaction term: the mean number of jurisdictions is 111 in the data set and therefore the average effect of decentralization is 0.44^{26} . Increasing the number of jurisdictions by 50 reduces the effect of decentralization on education by 0.1. Thus there is strong evidence that economies of scale have a strong positive impact in the context of decentralization.

A second measure of economies of scale is to look at the average population size per local jurisdiction. This measure captures those aspects of scale economies that are a function of population size. We find no evidence, as reported in column (2) of Table 4, for a differential effect of decentralization when the population per local county changes.

3.4. Local Cost Shares

We now want to explore if differential incentives are induced by variations in the local cost shares of teacher salaries. One could argue that a highly decentralized canton with a low

²⁵An alternative measure is to use population per jurisdiction which yields qualitatively similar results to the one presented in Table 6. Similarly the estimated effect is robust to the inclusion of population size as an additional control variable.

²⁶Calculated as $0.6619 - 111 \times 0.00199$.

Table 4 – Decentralization, Economies of Scale, Local Autonomy, and Budgetary Competence

Dependent variable = Share of 19 year old population obtaining university entry qualification (Maturité rate)
 Robust standard errors reported in parentheses, allowing for clustering at canton level

	Number of local jurisdictions (1)	Population size per jurisdiction (2)	Budgetary Competence (3)	Business Cycle (4)
Decentralization <i>average of past 5 years</i>	0.6619** (.2547)	0.3920** (.1776)	0.6380** (.2655)	0.6356** (.2647)

Expenditure per pupil <i>average of past 12 years</i>	0.1080** (.0427)	0.1097** (.0427)	0.1040** (.0427)	0.1061** (.0410)
Business Cycle				0.0001 (0.0004)
Canton fixed effects	Yes	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes	Yes
Errors clustered at canton level	Yes	Yes	Yes	Yes
Adjusted R-squared	0.9554	0.9544	0.9562	0.9562
Number of observations	208	208	208	208

Notes: * significant at 10% level, ** at 5% level, *** at 1% level. In column 3 and 4 we first eliminated the cyclical component of the underlying budget surplus data using the Hodrick-Prescott (1997) filter with $\lambda=1600$, where λ is a parameter penalizing variability in the underlying growth component series. Results are robust to alternative values of λ . In column (4) we measure business cycles as the *cyclical* part of canton-level GDP per capita using the Hodrick-Prescott (1997) filter with $\lambda=1600$. Results in column (3) and (4) are robust to using the raw budget data instead of the smoothed data.

cost share may be more willing to make policy changes to improve educational attainment given that it will only partially have to bear the financial consequences of their decisions. Equally, a canton that has a high degree of decentralization but also a high local cost share may be less willing to implement changes as they will have to cover more of the financial cost. To see if there is empirical support for this argument we introduce an interaction term between the level of decentralization in a canton, $D_{ct}^{t-1,t-5}$, and the local cost share LC_c .²⁷

$$E_{ct} = \alpha_c + \beta_t + \gamma D_{ct}^{t-1,t-5} + \rho(D_{ct}^{t-1,t-5} \times LC_c) + \eta X_{ct}^{t-1,t-12} + u_{ct}. \quad (3.5)$$

If a high local cost share would indeed inhibit the gains from decentralization then the coefficient on interaction term would be negative. As can be seen, however, in column (3) of Table 4 the coefficient on the interaction term is negative but not significant and moreover, when evaluated at the mean level of the interaction term, the coefficient on decentralization remains the same. Thus the effect of more decentralization is not affected by how much the local governments have to contribute to the financing of their policies.

3.5. Decentralization and Budgetary Competence

A further criticism of decentralization is that the competence of local politicians standing for election may be lower than those standing for positions in the central government. This may be due to the fact that holding an office at the local government is less prestigious than at the central government. These issues can be particularly acute in the context of developing countries, as discussed in Bardhan (2002), where the competence of local public officials is often low. To assess this second argument we follow the methodology in Galiani and Schargrotsky (2001). In that paper, competence of a government is proxied by the size of the budgetary surplus. Low or negative surplus, i.e. deficit, is interpreted to be associated with less competent governments. In contrast to Galiani and Schargrotsky (2001) we have data not only on the level of budgetary surplus at the central but also at the local level. To assess the effect of decentralization jointly with the level of competence we estimate the following model:

$$E_{ct} = \alpha_c + \beta_t + \gamma D_{ct}^{t-1,t-5} + \nu_L(D_{ct}^{t-1,t-5} \times SL_{ct}) + \nu_C(D_{ct}^{t-1,t-5} \times SC_{ct}) + \eta X_{ct}^{t-1,t-12} + u_{ct} \quad (3.6)$$

Here SL_{ct} measures the budgetary surplus of all *local* governments in a canton as a percent of cantonal GDP; SC_{ct} measures the budgetary surplus of the *central* government

²⁷Recall that the level of local cost share only varies across cantons but is fixed across time.

as a percent of cantonal GDP. Thus v_L measures the effect of decentralizing *towards* local governments with a relatively high level of competence and v_C measures the effect of decentralizing *away from* a central government with a relatively high level of competence. Note that we continue to control for canton fixed effects which holds fixed levels of deficits that are determined by the financing structure in a canton. As there is a strong cyclical component in the budget data we first smoothed the underlying budget deficit data series using the Hodrick and Prescott (1997) filter.

In column (3) of Table 4 we report regression results on examining budgetary competence. We see that v_L is significantly different from zero and positive and v_C is insignificant. This is evidence that decentralizing *towards* a competent local government, increases the gains from expenditure decentralization. In column (4) we add a measure of canton level business cycle to address a potential further omitted variable bias. We measure the business cycle as the cyclical part of the per capita GDP in a canton using the Hodrick and Prescott (1997) filter. The results also remain the same if do not control for business cycles directly or in the underlying budget data. Thus there is evidence that decentralization is more effective when the local government is incompetent. This result gives support to the notion that competence - even in a developed country like Switzerland - needs to be taken into account when deciding on the degree of decentralization.

3.6. Adverse Effects of Decentralization

So far we have found evidence that decentralization is associated with better educational attainment as measured by Maturité rates. It is important, however, to test if these gains were accompanied by losses along other dimensions. We focus on two types of adverse effects.

3.6.1. Gender

First, we ask if these gains in educational attainment are gender specific, i.e. if the gains to one gender has been accompanied by losses for the other. There are various reasons why decentralization leads to more targeted outcomes. If decentralization is increasing responsiveness to the median voter in each region then the preferences of this voter will change the policy choice. Central governments on the other hand are argued to be more able to redistribute gains to minority interests that are less well represented at the local level. In the case of Switzerland, there are more women than men obtaining the Maturité as a share of 19 year old female and male population respectively. Table 5 presents panel regressions where now the dependent variable is the Maturité rate among women in column

Table 5 – Any Adverse Effects of Decentralization?

Robust standard errors reported in parentheses, allowing for clustering at canton level

	Dependent Variable: Maturite rate among women (1)	Dependent Variable: Maturite rate among men (2)	Dependent Variable: Professional school degrees (3)

Canton fixed effects	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes
Errors clustered at canton level	Yes	Yes	Yes
Adjusted R-squared	0.9483	0.9561	0.7313
Number of observations	182	182	208

Notes: * significant at 10% level, ** at 5% level, *** at 1% level. See Table A1 for definition of variables. The dependent variables are: in column (1) the number of women obtaining the maturite degree as a share of 19 year old women; in column (2) the number of men obtaining the maturite degree as a share of 19 year old men; in column (3) the number of students obtaining the professional school degree as a share of 19 year old population.

(1) and the Maturité rate among men in column (2).²⁸ For the case of female educational attainment, decentralization has a positive effect but it is not statistically significant. Only expenditure is significantly related to the female Maturité rate. In column (2) we repeat the same exercise but now for male students only. Here decentralization has a strong and significant effect on men; equally the economy of scale affect and the budgetary competence effect only comes into play for male students but not for female students. Given that the gains have accrued more to men than to women we also estimated a gender education gap model - not reported but available on request - where we do indeed find some evidence that decentralization reduced the gender gap in education.

3.6.2. Professional degrees

Second, we assess if the gains in terms of Maturité rates has been accompanied by a decline at other degrees. Among post-compulsory education the modal group of students attends professional schools rather than Maturité schools. For instance in 2000 17% of 19 year old students obtained the Maturité but 57% obtained a degree from a professional school. In column (3) of Table 5 we estimate a model where the dependent variable is the share of 19 year olds that obtain a degree from a professional school. We find that decentralization had no effect on that level of education.

In summary, we find no evidence for adverse effects of decentralization. More local expenditure is associated with better education among men but that has not been to the detriment of education among women and we find evidence that is reduced the gender gap in education for the Maturité. Similarly other degrees like those obtained from professional schools are not related to decentralization. Therefore it seems that decentralization is associated with a net gain in terms of educational attainment.

4. Conclusions

We investigated the empirical evidence on the relationship between decentralization and the efficiency of public good provision. As a first step we looked at the current legislation in the Swiss cantons to provide careful evidence on the positive relation between expenditure decentralization and local autonomy in decision, and also describing the sources of variation in expenditure decentralization over time. We then proceeded to panel regressions of data from Swiss cantons for the last 20 years. We saw that even after controlling

²⁸The sample is somewhat smaller as educational attainment by canton and gender is not available for the year 2000.

for other input variables the degree of decentralization is positively related to educational attainment. We take this to be novel and consistent evidence that contradicts earlier cross-section findings that decentralization worsens governance (Treisman, 2002). Indeed it is the quality of data and the correct specification of the model that helps to uncover the precise effect of decentralization on the efficiency of public good provision.

We also find evidence that expenditure decentralization is more beneficial when central governments are less competent. These results shed new light on the empirical relevance of decentralization and the conditions under which it can attain its often claimed aim of improving the efficiency of public good provision. Future research should aim to further refine the institutional details under which decentralization is beneficial and to also take the data to a micro level to see which people benefit or lose most and under what conditions from decentralization.

Table A1 – Summary Statistics

The Data covers 26 Swiss Cantons during 1982-2000

Performance Measure for Public Education	Mean	St. Dev
Maturité rate		
Share of 19 year population with University entry level qualification	.164	.057
Female Maturité rate as a share of 19 year old women	.165	.074
Male Maturité rate as a share of 19 year old men	.161	.046
Professional School Degrees as a share of 19 year old population	.593	.134
Decentralization		
Share of local expenditure to all expenditure (local and central) <i>5 year moving average</i>	.610	.215
Number of local jurisdictions in a canton	111.38	111.74
Control Variables		
Education expenditure per pupil* (12 year moving average) at all levels of government in 1990 1000s of Swiss Francs	14.933	2.926
Class size in schools (12 year moving cantonal average)	32.60	3.29
Non-native speakers (12 year moving average) percent of students whose first language is not the language of instruction	16.30	8.13
Budget surplus as a percent of cantonal GDP (5 year moving average)		
-at the central (cantonal) government level	-.7825	.9249
-at the local government level	-.3655	.3825
Business Cycle		
Cyclical component of the canton-level GDP per capita using the Hodrick-Prescott (1997) filter	-789.44	2104.86

Notes: All data is from the Swiss Federal Statistical Office (various departments); <http://www.statistik.admin.ch>. *primary and secondary education excluding tertiary education.
