ANALYSIS OF PATCH-TEST CONSISTENT
ATOMISTIC-TO-CONTINUUM COUPLING WITH
HIGHER-ORDER FINITE ELEMENTS

A. S. DEDNER, C. ORTNER, AND H. WU

ABSTRACT. We formulate a patch test consistent atomistic-to-continuum coupling (a/c) scheme that employs a second-order (potentially higher-order) finite element method in the material bulk. We prove a sharp error estimate in the energy-norm, which demonstrates that this scheme is (quasi-)optimal amongst energy-based sharp-interface a/c schemes that employ the Cauchy–Born continuum model. Our analysis also shows that employing a higher-order continuum discretisation does not yield qualitative improvements to the rate of convergence.

1. Introduction

Atomistic-to-continuum (a/c) coupling is a class of coarse-graining methods for efficient atomistic simulations of systems that couple localised atomistic effects described by molecular mechanics with long-range elastic effects described by continuum models using the finite-element method. We refer to [6], and references therein for an extensive introduction and references.

The presented work explores the feasibility and effectiveness of introducing higher-order finite element methods in the a/c framework, specifically for quasi-nonlocal (QNL) type methods.

The QNL-type coupling, first introduced in [15], is an a/c method that uses a “geometric consistency condition” [3] to construct the coupling between the atomistic and continuum model. The first explicit construction of such a scheme for two-dimensional domains with corners is described in [12] for a nearest-neighbour many-body site potential. We call this construction ”G23” for future reference. This approach satisfies force and energy patch tests (often simply called consistency), which in particular imply absence of ghost forces.

We will supply the G23 scheme with finite element methods of different orders and investigate the rates of convergence for the resulting schemes. Our conclusion will be that second-order finite element schemes are theoretically superior to first-order schemes, while schemes of third and higher order do not improve the rate of convergence. This conclusion is independent of defect types, since the total error can only be as good as the Cauchy–Born modeling error in the continuum region, which is of second order, just as a P2-finite element method. We further find that the consistency error of the a/c scheme is in fact dominated by the coupling component of the modelling error. Because of all these limitations, we will explore, for a basic
model problem, how well second-order schemes fare in practise against first-order schemes.

1.1. Outline. The theory of high-order finite element methods (FEM) in partial differential equations, and applications in solid mechanics is well established; see [14] and references therein. However, most work on the rigorous error analysis of a/c coupling has been restricted to P1 finite element methods; the only exception we are aware of is [11], which focuses on blending-type methods.

In the present work we estimate the accuracy of a QNL method employing a P2 FEM in the continuum region against an exact solution obtain from a fully atomistic model. Since stability of QNL type couplings is a subtle issue [9] we will primarily analyse the consistency errors, taking into account the relative sizes of the fully resolved atomistic region and of the entire computational domain (Sections 6.1-6.6). We will then optimize these relative sizes as well as the mesh grading in the continuum region in order to minimize the total consistency error (Section 6.7). We will observe that, using P1-FEM in the continuum region, the error resulting from FEM approximations is the dominating contributor of the consistency estimates, which implies that increasing the order of the FEM can indeed improve the accuracy of the simulation. We will show that, using Pk-FEM with \( k \geq 2 \), the FEM approximation error is dominated by the interface error which comes purely from the G23 construction, and in particular demonstrate that the P2-FEM is sufficient to achieve the optimal convergence rate for the consistency error. Finally, assuming the stability of the G23 coupling (see assumption (A2) in § 3.2, and also [9] why this must be an assumption and cannot be proven), we prove a rigorous error estimate in §6.

Finally, we conduct numerical experiments on a 2D anti-plane model problem to test our analytical predictions. The numerical results display the predicted error convergence rates for the fully atomistic model, P1-FEM G23 model, and P2-FEM G23 model.

2. Preliminaries

Our setup and notation follows [12]. As our model geometry we consider an infinite 2D triangular lattice,

\[ \Lambda := A \mathbb{Z}^2, \quad \text{with} \quad A = \begin{pmatrix} 1 & \cos(\pi/3) \\ 0 & \sin(\pi/3) \end{pmatrix}. \]

We define the six nearest-neighbour lattice directions by \( a_1 := (1, 0) \), and \( a_j := Q_6^{j-1} a_1, j \in \mathbb{Z} \), where \( Q_6 \) denotes the rotation through the angle \( \pi/3 \). We supply \( \Lambda \) with an atomistic triangulation, as shown in Figure 1, which will be convenient in both analysis and numerical simulations. We denote this triangulation by \( T \) and its elements by \( T \in T \). We also denote \( \mathbf{a} := (a_j)_{j=1}^6 \), and \( \mathbf{F} \mathbf{a} := (\mathbf{F}a_j)_{j=1}^6 \), for \( \mathbf{F} \in \mathbb{R}^{m \times 2} \).

We identify a discrete displacement map \( u : \Lambda \to \mathbb{R}^m \), \( m = 1, 2, 3 \), with its continuous piecewise affine interpolant, with weak derivative \( \nabla u \), which is also the pointwise derivative on each element \( T \in T \). For \( m = 1, 2, 3 \), the spaces of displacements are defined as

\[ \mathcal{U}_0 := \{ u : \Lambda \to \mathbb{R}^m : \text{supp}(\nabla u) \text{ is compact} \}, \quad \text{and} \]

\[ \mathcal{U}^{1,2} := \{ u : \Lambda \to \mathbb{R}^m : \nabla u \in L^2 \}. \]
We equip $\dot{U}^{1,2}$ with the $H^1$-seminorm, $\|u\|_{H^1} := \|\nabla u\|_{L^2(\Omega)}$. From [8] we know that $U_0$ is dense in $\dot{U}^{1,2}$ in the sense that, if $u \in \dot{U}^{1,2}$, then there exist $u_j \in U_0$ such that $\nabla u_j \rightarrow \nabla u$ strongly in $L^2$.

A homogeneous displacement is a map $u_F : \Lambda \rightarrow \mathbb{R}^m$, $u_F(x) := Fx$, where $F \in \mathbb{R}^{m \times 2}$.

For a map $u : \Lambda \rightarrow \mathbb{R}^m$, we define the finite difference operator

$$D_j u(x) := u(x + a_j) - u(x), \quad x \in \Lambda, j \in \{1, 2, \ldots, 6\}, \quad \text{and} \quad Du(x) := (D_j u(x))_{j=1}^6.$$  \hfill (2.1)

Note that $Du_F(x) = Fa$.

2.2. The variational problem. We add an external potential $f \in C^r(\dot{U}^{1,2})$ with $\partial_\ell f(u) = 0$ for all $|\ell| \geq R_f$, where $R_f$ is some given radius, and $f(u + c) = f(u)$ for all constants $c$. For example, we can think of $f$ modelling a substitutional impurity. See also [5, 7] for similar approaches.

We then seek the solution to

$$u_a \in \arg \min \{\mathcal{E}^a(u) - f(u) \mid u \in \dot{U}^{1,2}\}. \hfill (2.2)$$

---

**Figure 1.** The lattice and its canonical triangulation.
For \( u, \varphi, \psi \in \mathcal{U}^{1,2} \) we define the first and second variations of \( E^a \) by
\[
\langle \delta E^a(u), \varphi \rangle := \lim_{t \to 0} t^{-1} (E^a(u + t\varphi) - E^a(u)),
\]
\[
\langle \delta^2 E^a(u) \varphi, \psi \rangle := \lim_{t \to 0} t^{-1} (\langle \delta E^a(u + t\varphi), \psi \rangle - \langle \delta E^a(u), \psi \rangle).
\]
We use analogous definitions for all energy functionals introduced in later sections.

### 2.3. The Cauchy–Born Approximation

The Cauchy–Born strain energy function, corresponding to the interatomic potential \( V \), is
\[
W(F) := \frac{1}{\Omega_0} V(Fa), \quad \text{for } F \in \mathbb{R}^{m \times 2},
\]
where \( \Omega_0 := \sqrt{3}/2 \) is the volume of a unit cell of the lattice \( \Lambda \). Thus \( W(F) \) is the energy per volume of the homogeneous lattice \( F\Lambda \).

### 2.4. The G23 coupling method

Let \( \mathcal{A} \subset \Lambda \) denote the set of all lattice sites for which we want to maintain full atomistic accuracy. We denote the set of interface lattice sites by
\[
\mathcal{I} := \{ \ell \in \Lambda \setminus \mathcal{A} \mid \ell + a_j \in \mathcal{A} \text{ for some } j \in \{1, \ldots, 6\} \}
\]
and we denote the remaining lattice sites by \( \mathcal{C} := \Lambda \setminus (\mathcal{A} \cup \mathcal{I}) \). Let \( \Omega_\ell \) be the Voronoi cell associated with site \( \ell \). We define the atomistic, interface and continuum regions respectively by
\[
\Omega^a := \bigcup_{\ell \in \mathcal{A}} \Omega_\ell, \quad \Omega^i := \bigcup_{\ell \in \mathcal{I}} \Omega_\ell, \quad \text{and} \quad \Omega^c := \mathbb{R}^2 \setminus \bigcup_{\ell \in \mathcal{A} \cup \mathcal{I}} \Omega_\ell;
\]
see Figure 2 for a visualisation.

A general form for the GRAC-type a/c coupling energy \([3, 12]\) is
\[
E^{ac}(u) = \sum_{\ell \in \mathcal{A}} V(Du(\ell)) + \sum_{\ell \in \mathcal{I}} V \left( (\mathcal{R}_\ell D_j u(\ell))_{j=1}^6 \right) + \int_{\Omega^c} W(\nabla u(x)) \, dx,
\]
where \( \mathcal{R}_\ell D_j u(\ell) := \sum_{i=1}^6 C_{\ell,j,i} D_i u(\ell) \). The parameters \( C_{\ell,j,i} \) are to be determined in order for the coupling scheme to satisfy the "patch tests":

\( E^{ac} \) is **locally energy consistent** if, for all \( F \in \mathbb{R}^{m \times 2}, \)
\[
V^i(Fa) = V(Fa) \quad \forall \ell \in \mathcal{I}. \tag{2.3}
\]

\( E^{ac} \) is **force consistent** if, for all \( F \in \mathbb{R}^{m \times 2}, \)
\[
\delta E^{ac}(u_F) = 0, \quad \text{where} \quad u_F(x) := Fx. \tag{2.4}
\]
Figure 3. The first two configurations are allowed. The third configuration is not allowed as the interface atom at the corner has no nearest neighbour in the continuum region, and should instead be taken as an atomistic site.

Figure 4. The geometry reconstruction coefficients $\lambda_{x,j}$ at the interface sites.

$E^{ac}$ is patch test consistent if it satisfies both (2.3) and (2.4).

For the sake of brevity of notation we will often write $V^\ell_i(Du(\ell)) := V ((R^\ell D_j u(\ell))_{j=1}^{6})$. Following [12] we make the following standing assumption (see Figure 3 for examples).

(A0) Each vertex $\ell \in I$ has exactly two neighbours in $I$, and at least one neighbour in $C$.

Under this assumption, the geometry reconstruction operator $R^\ell$ is then defined by

$$R^\ell D_j y(\ell) := (1 - \lambda_{t,j})D_{j-1} y(\ell) + \lambda_{t,j} D_j y(\ell) + (1 - \lambda_{t,j}) D_{j+1} y(\ell),$$

$$\lambda_{x,j} := \begin{cases} 2/3, & x + a_j \in C \\ 1, & \text{otherwise} \end{cases}.$$  

see Figure 4. The resulting coupling method is called G23 and the corresponding energy functional $E^{g23}$. This choice of coefficients (and only this choice) leads to patch test consistency (2.3) and (2.4).

For future reference we decompose the canonical triangulation $T$ as follows:

$$\begin{align*}
T_A := & \{ T \in T \mid T \cap (I \cup C) = \emptyset \}, \\
T_C := & \{ T \in T \mid T \cap (I \cup A) = \emptyset \}, \\
T_I := & T \setminus (T_C \cup T_A). 
\end{align*}$$
2.5. **Notation for a P2 finite element scheme.** In the atomistic and interface regions, the interactions are represented by discrete displacement maps, which are identified with their linear interpolant. Here, we identify the displacement map with its P1 interpolant. No approximation error is committed.

On the other hand, in the continuum region where the interactions are approximated by the Cauchy–Born energy, we could increase the accuracy by using \( P^p \)-FEM with \( p > 1 \). In later sections we will review that the Cauchy–Born approximation yields a 2nd-order error, whereas employing the P1-FEM in the continuum region would reduce the accuracy to first order. In fact, we will show in that, with optimized mesh grading, P2-FEM is sufficient to obtain a convergence rate that cannot be improved by other choices of continuum discretisations. High-order \( P^p \)-FEM with \( p > 2 \) will increase the computational costs but yield the same error convergence rate (see §3.5).

Let \( K > 0 \) denote the inner radius of the atomistic region,

\[
K := \sup \{ r > 0 \mid B_r \cap \Lambda \subset A \},
\]
where \( B_r \) denotes the ball of radius \( r \) centred at 0. In order for the defect to be contained in the atomistic region we assume throughout that \( K \geq R_f \).

Let \( \Omega_h \) denote the entire computational domain and \( N > 0 \) denote the inner radius of \( \Omega_h \), i.e.,

\[
N := \sup \{ r > 0 \mid B_r \subset \Omega_h \}.
\]

Let \( \mathcal{T}_h \) be a finite element triangulation of \( \Omega_h \) which satisfies that, for \( T \in \mathcal{T}_h \), \( T \) is closed and

\[
T \cap (A \cup I) \neq \emptyset \quad \Rightarrow \quad T \in \mathcal{T}.
\]
In other words, \( \mathcal{T}_h \) and \( \mathcal{T} \) coincide in the atomistic and interface regions, whereas in the continuum region the mesh size may increase towards the domain boundary. The optimal rate at which the mesh size increases will be determined in later sections.

We note that the concrete construction of \( \mathcal{T}_h \) will be based on the choice of the domain parameters \( K \) and \( N \); hence, when emphasizing this dependence, we will write \( \mathcal{T}_h(K,N) \). We assume throughout that the family \( (\mathcal{T}_h(K,N))_{K,N} \) is uniformly shape-regular, i.e., there exists \( c > 0 \) such that,

\[
diam(T)^2 \leq c|T|, \quad \forall T \in \mathcal{T}_h(K,N), \forall K \leq N.
\] (2.6)

This assumption eliminates the possibility of extreme angles on elements, which would deteriorate the constants in finite element interpolation error estimates. For the most part we will again drop the parameters from the notation by writing \( \mathcal{T}_h \equiv \mathcal{T}_h(K,N) \) but implicitly will always keep the dependence.

Similar to (2.5), we define the atomistic, interface and continuum elements as \( \mathcal{T}_h^a \), \( \mathcal{T}_h^i \) and \( \mathcal{T}_h^c \), respectively. Note that \( \mathcal{T}_h^a = \mathcal{T}_A \) and \( \mathcal{T}_h^i = \mathcal{T}_I \). We also let \( N_h \) denote the number of degrees of freedom of \( \mathcal{T}_h \).

We define the finite element space of admissible displacements as

\[
\mathcal{U}_h := \{ u \in C(\mathbb{R}^2;\mathbb{R}^m) \mid \text{supp}(u) \subset \Omega_h, u|_T \in \mathbb{P}^1(T) \text{ for } T \subset \mathcal{T}_h^a \cup \mathcal{T}_h^i \text{ and } u|_T \in \mathbb{P}^2(T) \text{ for } T \subset \mathcal{T}_h^c \}.
\] (2.7)

In defining \( \mathcal{U}_h \) we have made two approximations to the class of admissible displacements: (1) truncation to a finite computational domain and (2) finite element coarse-graining.
The computational scheme is to find
\[ u_h^{g23} \in \arg \min \{ E^{g23}(u_h) - f(u_h) \mid u_h \in U_h \}. \] (2.8)

**Remark 2.2.** \( U_h \) is embedded in \( U_0 \) via point evaluation. Through this identification, \( f(u_h) \) is well-defined for all \( u_h \in U_h \).

We will make this identification only when we evaluate \( f(u_h) \). The reason for this is a conflict when interpreting elements \( u_h \) as lattice functions is that we identify lattice functions with their continuous interpolants with respect to the canonical triangulation \( T \), which would be different from the function \( u_h \) itself. However, for the evaluation of \( f(u_h) \) this issue does not arise. \( \square \)

## 3. Summary of results

### 3.1. Regularity of \( u^a \)

The approximation error analysis in later sections requires estimates on the decay of the elastic fields away from the defect core. These results follow from a natural stability assumption:

(A1) The atomistic solution is strongly stable, that is, there exists \( C_0 > 0 \),
\[ \langle \delta^2 E^a(u^a) \varphi, \varphi \rangle \geq C_0 \| \nabla \varphi \|^2_{L^2}, \quad \forall \varphi \in \tilde{U}^{1,2}, \] (3.1)
where \( u^a \) is a solution to (2.2).

**Corollary 3.1.** Suppose that (A1) is satisfied, then there exists a constant \( C > 0 \) such that, for \( 1 \leq j \leq r - 2 \),
\[ |D^j u^a(\ell)| \leq C|\ell|^{1-j}. \]

**Proof.** See Theorem 2.3 in [4]. \( \square \)

### 3.2. Stability

In [9] it is shown that there is a “universal” instability in 2D interfaces for QNL-type a/c couplings: it is impossible to prove in full generality that \( \delta^2 E^{g23}(u^a) \) is a positive definite operator, even if we assume (3.1). Indeed, this potential instability is universal to a wide class of generalized geometric reconstruction methods. However, it is rarely observed in practice. To circumvent this difficulty, we make the following standing assumption:

(A2) The homogeneous lattice is strongly stable under the G23 approximation, that is, there exists \( C_{g23}^0 > 0 \) which is independent of \( K \) such that, for \( K \) sufficiently large,
\[ \langle \delta^2 E^{g23}(0) \varphi_h, \varphi_h \rangle \geq C_{g23}^0 \| \nabla \varphi_h \|^2_{L^2}, \quad \forall \varphi_h \in U_h. \] (3.2)

Since (3.2) does not depend on the solution it can be tested numerically. But a precise understanding under which conditions (3.2) is satisfied is still missing. In [9] a method of stabilizing 2D QNL-type schemes with flat interfaces is introduced, which could replace this assumption, however we are not yet able to extend this stabilizing method for interfaces with corners, such as the configurations discussed in this paper.
3.3. Main results. To state the main results it is convenient to employ a smooth interpolant to measure the regularity of lattice functions. In Lemma 6.1, we define such an interpolant \( \tilde{u} \in C^{2,1}(\mathbb{R}^2) \) for \( u \in \mathcal{U}_0 \), for which there exists a universal constant \( \tilde{C} \) such that, for all \( q \in [1, \infty] \), \( 0 \leq j \leq 3 \),

\[
|D^j u(\ell)| \leq \tilde{C} \|\nabla^j \tilde{u}\|_{L^1(\omega_\ell)} \quad \text{and} \quad \|\nabla^j \tilde{u}\|_{L^q(\mathbb{T})} \leq \tilde{C} \|D^j u\|_{L^q(\mathbb{T}^d)}
\]

where \( \omega_\ell := \ell + A(-1, 1)^2 \).

3.3.1. Consistency error estimate. In (5.6) we define a quasi-best approximation operator \( \Pi_h : \mathcal{U}_0 \to \mathcal{U}_h \), which truncates an atomistic displacement to enforce the homogeneous Dirichlet boundary condition, and then interpolates it onto the finite element mesh.

Our main result is the following consistency error estimate.

**Theorem 3.2.** If \( u^a \) is a solution to (2.2) then we have, for all \( \varphi_h \in \mathcal{U}_h \),

\[
\langle \delta \mathcal{E}_{\Xi}^{3,2}(\Pi_h u^a), \varphi_h \rangle \lesssim \left( \|\nabla^2 \tilde{u}^a\|_{L^2(\Omega^c)} + \|\nabla^3 \tilde{u}^a\|_{L^2(\Omega)} + \|\nabla^2 \tilde{u}^a\|_{L^4(\Omega^c)}^2 \right)
+ \|h^2 \nabla^3 \tilde{u}^a\|_{L^2(\Omega^c)} + \|\nabla \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})}
+ N^{-1} \|h^2 \nabla^2 \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})} \|\nabla \varphi_h\|_{L^2(\mathbb{R}^2 \setminus \Omega)}\]

where \( \Omega^c_h \) corresponds to the continuum region of \( \Omega_h \), and \( h(x) := \text{diam}(T) \) with \( x \in T \in T_h \).

3.3.2. Optimizing the approximation parameters. Before we estimate the error \( \|\nabla u^a - \nabla u_h\|_{L^2} \), we optimize the approximation parameters in the computational scheme. This means that the radius \( K \) of the atomistic region, the radius \( N \) of the entire computational domain and the mesh size \( h \) should satisfy certain balancing relations. We only outline the result of this optimisation and refer to § 6.7 for the details.

Due to the decay estimates on \( \tilde{u}^a \) the dominating terms in (3.3) turn out to be

\[
\|\nabla^2 \tilde{u}^a\|_{L^2(\Omega^c)} \quad \text{and} \quad \|\nabla \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})}.
\]

(We will see momentarily that the mesh size plays a minor role.) These two terms result from the nature of the coupling scheme and the far-field truncation error. In particular, both of these cannot be improved by the choice of discretisation of the Cauchy–Born model, e.g., order of the FEM. We also note that, if we had employed a P1-FEM, the only different terms in the analog of (3.3) are \( \|h \nabla^2 \tilde{u}^a\|_{L^2(\Omega^c)} \) rather than \( \|h^2 \nabla^3 \tilde{u}^a\|_{L^2(\Omega)} \), and \( N^{-1} \|h \nabla \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})} \) rather than \( N^{-1} \|h^2 \nabla^2 \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})} \), hence the limiting factor would have been \( \|h \nabla^2 \tilde{u}^a\|_{L^2(\Omega^c)} \).

We can balance the two terms in (3.4) by choosing \( N \approx K^{3/2} \). It then remains to determine a mesh-size so that the finite element error contribution,

\[
\|h^2 \nabla^3 \tilde{u}^a\|_{L^2(\Omega^c_h)} \quad \text{and} \quad N^{-1} \|h^2 \nabla^2 \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus B_{N/2})}
\]

remains small in comparison. We show that the scaling \( h(x) \approx \left( \frac{|x|}{K} \right)^{\beta} \) is a suitable choice, with \( 1 < \beta < 3/2 \), under which both terms become of order \( O(K^{-3}) \).

Thus, we have determined the approximation parameters \( (K, N, h) \) in terms of a single parameter \( K \). The quasi-optimal relations for P2-FEM discretisation of the Cauchy–Born model are summarised in Table 1.
Table 1. Quasi-optimal relations between approximation parameters for P2-GR23 and, for comparison, for P1-GR23.

Corollary 3.3. Suppose that $N, h$ satisfy the relations of Table 1, the consistency error estimate (3.3) in terms of the number of degrees of freedom $\mathcal{N}_h$ can be written as

$$\|\delta E^{g23}(\Pi_h u^a)\|_{\mathcal{U}^{-1,2}} \lesssim \mathcal{N}_h^{-5/4}. \quad (3.5)$$

3.3.3. Error estimate. To complete our summary of results, we now use the Inverse Function Theorem to obtain error estimates for the strains and the energy.

Theorem 3.4. Suppose that $(A0)$, $(A1)$ and $(A2)$ are satisfied and that the quasi-optimal scaling of $N, h$ from Table 1 is satisfied. Then, for sufficiently large atomistic region size $K$, a solution $u^{g23}_h$ to (2.8) exists which satisfies the error estimates

$$\|\nabla u^a - \nabla u^{g23}_h\|_{L^2} \lesssim \mathcal{N}_h^{-5/4}, \quad \text{and} \quad (3.6)$$

$$\|[\mathcal{E}^a(u^a) - f(u^a)] - [\mathcal{E}^{g23}(u^{g23}_h) - f(u^{g23})]\| \lesssim \mathcal{N}_h^{-7/4}, \quad (3.7)$$

where $\mathcal{N}_h$ is the number of degrees of freedom.

Remark 3.5. The analogous estimates of P1-GR23 to (3.6) and (3.7) are $\mathcal{N}_h^{-1}$ and $\mathcal{N}_h^{-2}$ respectively.

3.4. Setup of the numerical tests. For our numerical tests, we consider an anti-plane displacement $u : \Lambda \to \mathbb{R}$. We choose a hexagonal atomistic region $\Omega^p$ with side length $K$ and one layer of atomistic sites outside $\Omega^p$ as the interface. To construct the finite element mesh, we add hexagonal layers of elements such that, for each layer $j$, $h(\text{layer } j) = (|x|/K)\beta$, with $\beta = 1.4$; see Figure 5. The procedure is terminated once the radius of the domain exceeds $N = \lceil K^{5/2} \rceil$. This construction guarantees the quasi-optimal approximation parameter balance to optimise the P2-FEM error. The derivation is given in Section 6.7.

In our tests we compare the P2-G23 method against

1. a pure atomistic model with clamped boundary condition: the construction of the domain is as in the P2-G23 method, but without continuum region;
2. a P1-G23 method: the construction is again identical to that of the P2-G23 method, but the P2-FEM in the definition of $\mathcal{U}_h$ is replaced by a P1-FEM. The same mesh scaling as for P2 is used (see also [3] where this is shown to be quasi-optimal).
The site potential is given by a nearest-neighbour embedded atom toy model,

\[ V(Du) := G \left( \sum_{i=1}^{6} \rho(|D_i u(\ell)|) \right) \]

with \( G(s) := s + \frac{1}{2}s^2 \) and \( \rho(r) := \sin^2(r\pi) \). This is a simplified anti-plane toy model as used in [4], which absorbs the pair interaction into the embedding term.

The external potential is defined by \( \langle f, u \rangle = 10(u(0,0) - u(1,0)) \), which can be thought of as an elastic dipole. A steepest descent method, preconditioned with a finite element Laplacian and fixed (manually tuned) step-size, is used to find a minimizer \( u_h^{23} \) of \( E_{g23}(u) - f(u) \), using \( u_h = 0 \) as the starting guess.

In order to compare the errors, we use a comparison solution with atomistic region size \( 3K \) and other computational parameters scaled as above.

The numerical results, with brief discussions, are shown in Figures 6–9. The two most important observations are the following:

1. The numerical tests confirm the analytical predictions for the energy-norm error, but the experimental rates for the energy error are better than the analytical rates. Similar observations were also made in [4].

2. With our specific setup, the improvement of the P2-GR23 over P1-GR23 is clearly observed when plotting the error against \( \#A \propto N_h \), but when plotted against \( N_h \) the improvement is only seen in the asymptotic regime. This indicates that further work is required, such as a posteriori adaption, to optimise the P2-GR23 in the pre-asymptotic regime as well.

3.5. **Extension to high-order FEM.** If we apply higher-order FEM in the continuum region, then to extend our error analysis we would need a smooth interpolant of \( u \in U_0 \) with higher regularity than \( \tilde{u} \in C^{2,1}(\mathbb{R}^2) \). A suitable extension given in [5] is, for arbitrary \( n \), a \( C^{n,1} \) piecewise polynomial of degree \( 2n + 1 \) with properties analogous to those stated in Lemma 6.1. The resulting higher-order decay rate \( |\nabla^j \tilde{u}^n(x)| \lesssim |x|^{-j-1} \) indicates that the use of high-order FEM could be beneficial.
Figure 6. Error in energy norm plotted against $\#A$. We clearly observe the predicted rate of convergence.

Figure 7. Error in energy norm plotted against the number of degrees of freedom. The improvement of P2-FEM is now only seen asymptotically.
Figure 8. The energy error plotted against $\# \mathcal{A}$. The observed rate of convergence is better than the rate predicted in Theorem 3.4.

Figure 9. The energy error plotted against the number of degrees of freedom. The improvement of P2-FEM over P1-FEM can again only be observed asymptotically.
However, as we have pointed out in § 3.3.2, if we employ the mesh grading \( h(x) = \left(\frac{|x|}{K}\right)^\beta \) with \( 1 < \beta < 3/2 \) in the continuum region, the total approximation error cannot be improved by using \( P^p \)-FEM with \( p > 2 \), since the dominating term is the interface error \( \| \nabla^2 \tilde{u}^a \|_{L^2(\Omega)} \) for \( p \geq 2 \), which results from the construction of G23 coupling and is not affected by the choice of FEM.

If we consider a coarser mesh for high-order FEM in hopes of reducing the number of degrees of freedom, i.e., choosing \( \beta \geq 3/2 \), then applying analogous calculations to those in § 6.7 gives us the following result:

Employing \( P^p \)-FEM with \( p > 2 \), in order to match the convergence rate of the Cauchy–Born error term \( \| \nabla^3 \tilde{u}^a \|_{L^2(\Omega')} \sim K^{-3} \), the highest mesh coarsening rate is

\[
\beta = \frac{5}{3} - \frac{1}{3p}.
\]

This means that the optimal mesh grading that \( P^p \)-FEM can achieve without compromising accuracy is no greater than \( \frac{5}{3} \). However, in that case, the number of degrees of freedom is always \( \mathcal{O}(K^2) \).

4. Conclusion

We obtained a sharp energy-norm error estimate for the G23 coupling method with P2-FEM discretisation of the continuum model. Furthermore, we demonstrated that, with P1-FEM discretisation the FEM coarsening error is the dominating term in the consistency error estimate, whereas for P2-FEM discretisation the interface error becomes the dominating term. In particular, a P2-FEM discretisation yields a more rapid decay of the error. Crucially though, since for \( P^p \)-FEM with \( p \geq 2 \) the interface contribution dominates the total error the P2-FEM is already optimal. That is, increasing to \( p > 2 \) will not improve the rate of convergence, but increase the computational cost and algorithmic complexity.

Numerically, we observe that the improvement of P2-GR23 over P1-GR23 is only modest at moderate \( N_h \), hence a P2-GR23 scheme would be primarily of interest if very high accuracy of the solution is required. Purely according to our \textit{a priori} error analysis, considering the additional algorithmic complexity, it is unclear how practically useful higher-order FEM in the context of A/C coupling are. However, before drawing such a universal conclusion, one should explore whether optimising the pre-asymptotic regime, using \( hp \) a posteriori mesh adaption, could lead to improved cost/error rates.

While our estimates for the error in energy-norm are sharp, our numerical results show the estimates for the energy errors are suboptimal. We highlight the leading term in the error analysis which overestimate the error in Section 7.2. We are unable, at present, to obtain an optimal energy error estimate. This appears to be an open problem throughout the literature on hybrid atomistic multi-scale schemes; see e.g. [4].

In summary we conclude that using P2-FEM is a promising improvement to the efficiency of a/c coupling methods, but that some further work, both theoretical and for its implementation may be need to exploit its full potential.
5. Reduction to consistency

Assuming the existence of an atomistic solution \( u^a \), we seek to prove the existence of \( u^{g23}_h \in U_h \) satisfying

\[
\langle \delta \mathcal{E}^{g23}(u^{g23}_h), \varphi_h \rangle = \langle \delta f(u^{g23}_h), \varphi_h \rangle, \quad \text{for all } \varphi_h \in U_h,
\]

and to estimate the \( \| u^a - u^{g23}_h \| \) in a suitable norm.

The error analysis consists of consistency and stability estimates. Once these are established we apply the following theorem to obtain the existence of a solution \( u^{g23}_h \) and the error estimate. The proof of this theorem is standard and can be found in various references, e.g. [13, Lemma 2.2].

**Theorem 5.1 (The inverse function theorem).** Let \( U_h \) be a subspace of \( U \), equipped with \( \| \nabla \cdot \|_{L^2} \), and let \( \mathcal{G}_h \in C^1(U_h, U_h^*) \) with Lipschitz-continuous derivative \( \delta \mathcal{G}_h \):

\[
\| \delta \mathcal{G}_h(u_h) - \delta \mathcal{G}_h(v_h) \|_{L^2} \leq M \| \nabla u_h - \nabla v_h \|_{L^2} \quad \text{for all } u_h, v_h \in U_h,
\]

where \( \| \cdot \|_{L^2} \) denotes the \( L(U_h, U_h^*) \)-operator norm.

Let \( \bar{u}_h \in U_h \) satisfy

\[
\| \mathcal{G}_h(\bar{u}_h) \|_{U_h^*} \leq \eta, \quad \langle \delta \mathcal{G}_h(\bar{u}_h) v_h, v_h \rangle \geq \gamma \| \nabla v_h \|_{L^2}^2 \quad \text{for all } v_h \in U_h,
\]

such that \( M, \eta, \gamma \) satisfy the relation

\[
\frac{2M \eta}{\gamma^2} < 1.
\]

Then there exists a (locally unique) \( u_h \in U_h \) such that \( \mathcal{G}_h(u_h) = 0 \),

\[
\| \nabla u_h - \nabla \bar{u}_h \|_{L^2} \leq 2 \frac{\eta}{\gamma}, \quad \text{and}
\]

\[
\langle \delta \mathcal{G}_h(u_h) v_h, v_h \rangle \geq \left( 1 - \frac{2M \eta}{\gamma^2} \right) \gamma \| \nabla v_h \|_{L^2}^2 \quad \text{for all } v_h \in U_h.
\]

To ensure Dirichlet boundary conditions, we adapt the quasi-best approximation map defined in [4]. Let \( \mu \in C^3(\mathbb{R}^2) \) be a cut-off function such that

\[
\mu(x) = \begin{cases} 
1 & 0 \leq x \leq \frac{1}{2}, \\
0 & x \geq 1.
\end{cases}
\]

For \( u : \Lambda \to \mathbb{R}^m \), define

\[
\mathcal{L}u(x) := \mu \left( \frac{|x|}{N} \right) (\bar{u}(x) - a_u), \quad \text{where } a_u := \frac{1}{|B_N \setminus B_{N/2}|} \int_{B_N \setminus B_{N/2}} \bar{u}(y) \, dy.
\]

Let \( \nu_{T,i}, i = 1, 2, 3 \) be the vertices of \( T \) and \( m_e \) be the mid-point of an edge \( e \). Then, the set of all active P2 finite element nodes is given by

\[
\mathcal{N}_h := \{ \nu_{T,i} \mid T \in \mathcal{T}_h, i = 1, 2, 3 \} \cup \{ m_e \mid e = T_1 \cap T_2, T_1, T_2 \in \mathcal{T}_h \}.
\]

This includes all P1 nodes as well as the P2 nodes (edge midpoints) associated with edges entirely in the P2 region.
Furthermore, let $I_h^2 : C(\mathbb{R}^2; \mathbb{R}^m) \to \mathcal{U}_h$ be the interpolation operator such that, for $g \in C(\mathbb{R}^2; \mathbb{R}^m)$,
\[ I_h^2(g)|T \in \mathcal{P}^1(T) \text{ for } T \subset T_h^i \cup T_h^k, \]
and
\[ I_h^2(g)|T \in \mathcal{P}^2(T) \text{ for } T \subset T_h^c, \]
and
\[ I_h^2(g)(x) = g(x) \quad \text{for all } x \in \mathcal{N}_h. \]

**Remark 5.2.** We also introduce ghost nodes on the edges shared by interface and continuum elements:
\[ \mathcal{N}_h^g := \{ m \in \mathbb{N} \mid e = T_1 \cap T_2, T_1 \in T_h^i, T_2 \in T_h^c \}. \] (5.5)
Then, for $x \in \mathcal{N}_h^g$, $I_h^2(g)(x) = (g(\nu^1_e) + g(\nu^2_e))/2$, where $\nu^1_e$ and $\nu^2_e$ are the vertices of the edge on which $x$ lies. Hence, the $P^1$ and $P^2$ interpolants coincide on $\mathcal{N}_h^g$. \(\square\)

We can now define the projection map (quasi-best approximation operator) $\Pi_h : \mathcal{U}_0 \to \mathcal{U}_h$ as
\[ \Pi_h := I_h^2 \circ L. \] (5.6)

### 5.1. Stability
To put Theorem 5.1 (Inverse Function Theorem) into our context, let
\[ G_h(v) := \delta E^{g23}(v) - \delta f(v) \quad \text{and} \quad \bar{u}_h := \Pi_h u^a. \]
To make (5.2) and (5.3) concrete we will show that there exist $\eta, \gamma > 0$ such that, for all $\varphi_h \in \mathcal{U}_h$,
\[ \langle \delta E^{g23}(\Pi_h u^a), \varphi_h \rangle - \langle \delta f(\Pi_h u^a), \varphi_h \rangle \leq \eta \| \nabla \varphi_h \|_{L^2}, \quad \text{(consistency)} \]
\[ \langle \delta^2 E^{g23}(\Pi_h u^a), \varphi_h \rangle - \langle \delta^2 f(\Pi_h u^a), \varphi_h \rangle \geq \gamma \| \nabla \varphi_h \|_{L^2}^2, \quad \text{(stability)} \]
Ignoring some technical requirements, the inverse function theorem implies that, if $\eta/\gamma$ is sufficiently small, then there exists $u_h^{g23} \in \mathcal{U}_h$ such that
\[ \langle \delta E^{g23}(u_h^{g23}), \varphi_h \rangle - \langle \delta f(u_h^{g23}), \varphi_h \rangle = 0, \quad \forall \varphi_h \in \mathcal{U}_h, \quad \text{and} \]
\[ \| \nabla u_h^{g23} - \nabla \Pi_h u^a \|_{L^2} \leq 2 \frac{\eta}{\gamma}. \]

Finally adding the best approximation error $\| \nabla \Pi_h u^a - \nabla u^a \|_{L^2}$ gives the error estimate
\[ \| \nabla u_h^{g23} - \nabla u^a \|_{L^2} \leq \| \nabla \Pi_h u^a - \nabla u^a \|_{L^2} + 2 \frac{\eta}{\gamma}. \]

The Lipschitz and consistency estimates require assumptions on the boundedness of partial derivatives of $V$. For $g \in \mathbb{R}^{m \times 6}$, define the first and second partial derivatives, for $i, j = 1, \ldots, 6$, by
\[ \partial_j V(g) := \frac{\partial V(g)}{\partial g_j} \in \mathbb{R}^m, \quad \text{and} \quad \partial_{ij} V(g) := \frac{\partial^2 V(g)}{\partial g_i \partial g_j} \in \mathbb{R}^{m \times m}, \]
and similarly for the third derivatives $\partial_{ijk} V(g) \in \mathbb{R}^{m \times m \times m}$. We assume that the second and third derivatives are bounded
\[ M_2 : = \sum_{i,j=1}^{6} \sup_{g \in \mathbb{R}^{m \times 6}} \sup_{h_1, h_2 \in \mathbb{R}^2, |h_1|=|h_2|=1} \partial_{ij} V(g)[h_1, h_2] < \infty, \quad \text{and} \] (5.7)
\[ M_3 : = \sum_{i,j,k=1}^{6} \sup_{g \in \mathbb{R}^{m \times 6}} \sup_{h_1, h_2, h_3 \in \mathbb{R}^2, |h_1|=|h_2|=|h_3|=1} \partial_{ijk} V(g)[h_1, h_2, h_3] < \infty. \] (5.8)

With the above bounds it is easy to show that
Under the assumptions Lemma 5.4. \( L \) is the Lipschitz constant of the linear elasticity formulation of Cauchy–Born in the continuum region, and \( C \) is compactly supported hence \( \delta f \). The result follows directly from (5.9) and the fact that for \( \mathbf{g}, \mathbf{h} \in \mathbb{R}^{m \times 6} \).

Outline of the consistency estimate.

6.1. Consistency estimate with a P2-FEM. We begin by decomposing the consistency error into

\[
\sum_{i=1}^{6} |\partial_i V(\mathbf{g}) - \partial_i V(\mathbf{h})| \leq M_2 \max_{j=1,\ldots,6} |g_j - h_j|,
\]

\[
\sum_{i,j=1}^{6} |\partial_i \partial_j V(\mathbf{g}) - \partial_i \partial_j V(\mathbf{h})| \leq M_3 \max_{k=1,\ldots,6} |g_k - h_k|, \quad \text{for } \mathbf{g}, \mathbf{h} \in \mathbb{R}^{m \times 6}. \tag{5.9}
\]

From the bounds above we can obtain the following Lipschitz continuity and stability results.

Lemma 5.3. There exists \( M > 0 \) such that

\[
\| \delta \mathbf{g}_h(u_h) - \delta \mathbf{g}_h(v_h) \| \leq M \| \nabla u_h - \nabla v_h \|_{L^2} \quad \text{for all } u_h, v_h \in \mathcal{U}_h. \tag{5.10}
\]

Proof. The result follows directly from (5.9) and the fact that \( f \in C^r(\mathcal{U}^{1,2}) \) and that \( \delta f \) is compactly supported hence \( \delta^2 f \) is also Lipschitz. Namely, for all \( \varphi_h \in \mathcal{U}_h, \)

\[
\langle (\delta \mathbf{g}_h(u_h) - \delta \mathbf{g}_h(v_h)) \varphi_h, \varphi_h \rangle = \langle (\delta^2 \mathcal{E}^{23}(u_h) - \delta^2 \mathcal{E}^{23}(v_h)) \varphi_h, \varphi_h \rangle + \langle (\delta^2 f(v_h) - \delta^2 f(u_h)) \varphi_h, \varphi_h \rangle \leq C_{g23} M_3 \| \nabla u_h - \nabla v_h \|_{L^\infty} \| \nabla \varphi_h \|^2_{L^2} + C_f \| u_h - v_h \|_{L^\infty(B_{R_f})} \| \varphi_h \|^2_{L^2} \lesssim \| \nabla u_h - \nabla v_h \|_{L^2} \| \nabla \varphi_h \|^2_{L^2} + \| \nabla u_h - \nabla v_h \|_{L^2(B_{R_f})} \| \varphi_h \|^2_{L^2},
\]

where \( C_{g23} \) is the constant resulting from the interface reconstruction and the linear elasticity formulation of Cauchy–Born in the continuum region, and \( C_f \) is the Lipschitz constant of \( \delta^2 f \).

Lemma 5.4. Under the assumptions (A1) and (A2), if \( \mathbf{g}_h(v) := \delta \mathcal{E}^{23}(v) - \delta f(v) \), then there exists \( \gamma > 0 \) such that, when \( K \) is sufficiently large,

\[
\langle \delta \mathbf{g}_h(\Pi_h u^a), \varphi_h \rangle \geq \gamma \| \nabla \varphi_h \|^2_{L^2} \quad \text{for all } \varphi_h \in \mathcal{U}_h. \tag{5.11}
\]

Proof. The proof of this result is a straightforward adaption of the proof of [5, Lemma 4.9], which is an analogous result for blending-type a/c coupling.

6. Consistency estimate with a P2-FEM

6.1. Outline of the consistency estimate. We begin by decomposing the consistency error into

\[
\langle \delta \mathcal{E}^{23}(\Pi_h u^a), \varphi_h \rangle - \langle \delta f(\Pi_h u^a), \varphi_h \rangle = \left\{ \langle \delta \mathcal{E}^{23}(\Pi_h u^a), \varphi_h \rangle - \langle \delta \mathcal{E}^a(u^a), \varphi \rangle \right\} + \left\{ \langle \delta f(\Pi_h u^a), \varphi_h \rangle - \langle \delta f(u^a), \varphi \rangle \right\} =: \eta_{\text{int}} + \eta_{\text{ext}}, \tag{6.1}
\]

where \( \varphi_h \in \mathcal{U}_h \) is given and we can choose \( \varphi \in \mathcal{U}_0 \) arbitrarily.

For \( \varphi_h \in \mathcal{U}_h, \varphi_h |_T \in \mathbb{P}^2(T) \) for \( T \in T_h^e \). But the test function \( \varphi \) in \( \langle \delta \mathcal{E}^a(u^a), \varphi \rangle \) is a piecewise linear lattice function. While we postpone the construction of \( \varphi \), we will ensure that it is defined in such a way that \( \varphi(\ell) = \varphi_h(\ell) \) for all \( \ell \in \mathcal{A} \cup \mathcal{I} \cup \mathcal{I}^e \).
where \( I^+ \) is an extra layer of atomistic sites outside \( I \). With this assumption in place, we can further decompose \( \eta_{\text{int}} \) into the following parts,

\[
\eta_{\text{int}} = \int_{I^c} \partial_T W(\nabla \tilde{u}^a) : (\nabla \varphi_h - \nabla \varphi) + \int_{I^c} (\partial_T W(\nabla \Pi_h u^a) - \partial_T W(\nabla \tilde{u}^a)) : \nabla \varphi_h + \int_{I^c} [\partial_T W(\nabla \tilde{u}^a) - \partial_T W(\nabla u^a)] : \nabla \varphi + \langle \delta \xi_{\text{H}}(u^a) - \delta \xi_h(u^a), \varphi \rangle =: \delta_1 + \delta_2 + \delta_3 + \delta_4,
\]

where \( \tilde{u}^a \) is the smooth interpolant of \( u^a \) defined in Lemma 6.1 below. By \( \nabla \varphi \) in \( \delta_1 \) we mean the gradient of the canonical linear interpolant of \( \varphi \). To estimate \( \delta_2 \) we require an approximation error estimate for \( \Pi_h u - u \). To estimate \( \delta_3 \) we will exploit the fact that the atomistic triangulation \( T \) is uniform to prove a super-convergence estimate. Finally, for the modelling error, \( \delta_4 \), we employ the techniques developed in [12].

To define the smooth interpolant \( \tilde{u}^a \), we use the construction from [5], namely a \( C^{2,1} \)-conforming multi-quintic interpolant. Although the interpolant defined in [5] is for lattice functions on \( \mathbb{Z}^2 \), we can use the linear transformation from \( \mathbb{Z}^2 \) to \( \Lambda = A\mathbb{Z}^2 \) to obtain a modified interpolant.

**Lemma 6.1.**  (a) For each \( u : \Lambda \to \mathbb{R}^m \), there exists a unique \( \tilde{u} \in C^{2,1}(\mathbb{R}^2; \mathbb{R}^m) \) such that, for all \( \ell \in \Lambda \),

\[
\tilde{u}|_{\ell+A(0,1)^2} \text{ is a polynomial of degree 5,}
\]

\[
\tilde{u}(\ell) = u(\ell),
\]

\[
\partial_{a_i} \tilde{u}(\ell) = \frac{1}{2} (u(\ell + a_i) - u(\ell - a_i)),
\]

\[
\partial_{a_i}^2 \tilde{u}(\ell) = u(\ell + a_i) - 2u(\ell) + u(\ell - a_i),
\]

where \( i \in \{1, 2\} \) and \( \partial_{a_i} \) is the derivative in the direction of \( a_i \).

(b) Moreover, for \( q \in [1, \infty], 0 \leq j \leq 3 \),

\[
\|\nabla^j \tilde{u}\|_{L^q(\ell+A(1,0)^2)} \lesssim \|D^j u\|_{L^q(\ell+A(-1,1)^2)} \quad \text{and} \quad |D^j u(\ell)| \lesssim \|\nabla \tilde{u}\|_{L^q},
\]

where \( D \) is the difference operator defined in (2.1). In particular,

\[
\|\nabla \tilde{u}\|_{L^q} \lesssim \|\nabla u\|_{L^q} \lesssim \|\nabla \tilde{u}\|_{L^q},
\]

where \( u \) is identified with its piecewise affine interpolant.

**Proof.** Let \( v : \mathbb{Z}^2 \to \mathbb{R}^m \) and \( v(\xi) := u(A\xi) \) for all \( \xi \in \mathbb{Z} \). Then [5, Lemma 1] shows that there exists a unique \( \tilde{v} \in C^{2,1}(\mathbb{R}^2; \mathbb{R}^m) \) such that, for \( \xi \in \mathbb{Z}^2 \),

\[
\tilde{v}|_{\xi+(0,1)^2} \text{ is a polynomial of degree 5,}
\]

\[
\tilde{v}(\xi) = v(\xi),
\]

\[
\partial_{a_i} \tilde{v}(\xi) = \frac{1}{2} (v(\xi + e_i) - v(\xi - e_i)),
\]

\[
\partial_{a_i}^2 \tilde{v}(\xi) = v(\xi + e_i) - 2v(\xi) + v(\xi - e_i) \quad i = 1, 2,
\]

Defining \( \tilde{u}(x) := \tilde{v}(A^{-1}x) \) for all \( x \in \mathbb{R}^2 \) proves part (a).
For part (b), [5, Lemma 1] establishes also that there exists a constant $C_j''$ such that, for $\xi \in \mathbb{Z}^2$, $1 \leq j \leq 3$, $q \in [1, \infty]$, 

$$\|\nabla^j \hat{v}\|_{L^q(\xi+(1,0)^2)} \leq C_j'' \|\hat{D}^j v\|_{L^q(\xi+(-1,0,1,2)^2)},$$

where $\hat{D}$ represents the 4-stencil difference operator in $\mathbb{Z}^2$: let $R := \{\rho \in \mathbb{Z}^2 \mid |ho| = 1\}$, then $\hat{D}v(\ell) := \hat{D}_\rho v(\ell)$ for $\rho \in R$. After transformation, we have, for $\xi = A\ell \in \Lambda$,

$$\hat{D}v(\ell) = (D_i u(\xi))_{i=1,2,4,5}.$$

By adding the additional stencil elements $D_3, D_6$ we obtain

$$C_j'' \|\nabla^j \tilde{u}\|_{L^q(\xi+A(1,0)^2)} \leq \|\nabla^j \hat{v}\|_{L^q(\xi+1,0)^2)} \leq C_j'' \|\hat{D}^j v\|_{L^q(\xi+(-1,0,1,2)^2)} \leq C_j''' \|\hat{D}^j v\|_{L^q(\xi+\Lambda(-1,0,1,2)^2)},$$

where $C_j''$ and $C_j'''$ only depend on $j$. Writing $C := \max_{1 \leq j \leq 3} \left(\frac{C_j'''}{C_j''}\right)$ yields the first inequality of (6.3). Following a similar argument the second inequality also holds. \hfill \Box

### 6.2. Construction of $\varphi$ and estimation of $\delta_1$.

Recall that

$$\delta_1 := \int_{\partial R} \partial F \left(\nabla \bar{u}^a \right) \cdot (\nabla \varphi_h - \nabla \varphi).$$

We adapt the modified quasi-interpolation operator introduced in [2] to approximate a test function $\varphi_h \in U_h$. The advantage of this interpolation operator is that by using the setting of a partition of unity the approximation error has a local average zero. Consequently we can apply Poincaré inequality on patches to obtain local estimates.

We think of the construction of $\varphi$ as a Dirichlet boundary problem with the outer boundary $\partial \Omega_h$ and the inner boundary $\partial \Omega^c$. Let $\phi_\ell$ be the piecewise linear hat-functions on the canonical triangulation $\mathcal{T}$ associated with $\ell \in \Lambda$. Define

$$\phi^\text{PU}_\ell := \frac{\phi_\ell}{\sum_{k \in C \cap \Omega_h} \phi_k}, \quad \forall \ell \in \mathcal{C},$$

where $\mathcal{C}$ is the continuum lattice sites as defined in §2.4. It is clear that $\{\phi^\text{PU}_\ell\}_{\ell \in C \cap \Omega_h}$ is a partition of unity.

Now we refer to [2] for the construction of a linear interpolant of $\varphi_h \in U_h$. We shall define the interpolant as follows:

$$\Pi_h \varphi_h(x) := \varphi(x) := \varphi_1(x) + \varphi_2(x), \quad \forall x \in \mathbb{R}^2, \quad (6.4)$$
where
\[ \varphi_1(\ell) := \begin{cases} \varphi_h(\ell), & \ell \in A \cup I \cup I^+, \\ \frac{f_{k^2} \varphi_{\ell h}}{f_{k^2} \varphi_{\ell}}, & \ell \in C \setminus I^+, \end{cases} \]
\[ \varphi_1(x) := \sum_{\ell \in \Lambda} \varphi_1(\ell) \phi_\ell(x), \quad \forall x \in \mathbb{R}^2, \]
\[ \varphi_2(\ell) := \begin{cases} \frac{f_{k^2}(\varphi_h - \varphi_1)\sigma_{\ell}^{PU}}{f_{k^2} \varphi_{\ell}}, & \ell \in C \setminus I^+, \\ 0, & \ell \in A \cup I \cup I^+, \end{cases} \]
\[ \varphi_2(x) := \sum_{\ell \in \Lambda} \varphi_2(\ell) \phi_\ell(x), \quad \forall x \in \mathbb{R}^2. \]

Observe that \( \varphi_h \) and \( \varphi \) both are supported on a finite domain, hence we can use Theorem 3.1 in [2] to conclude that
\[ \| \nabla \varphi \|_{L^2(\mathbb{R}^2)} \lesssim \| \nabla \varphi_h \|_{L^2(\mathbb{R}^2)}, \quad \forall \varphi_h \in \mathcal{U}_h. \]

Let \( g := -\text{div} [\partial_{\ell} W(\nabla \tilde{u}^a)] \). Then
\[ \delta_1 = \int_{\Omega^c} g \cdot (\varphi_h - \varphi) \, dx = \int_{\Omega^c} g \cdot ((\varphi_h - \varphi_1) - \varphi_2) \, dx \]
Since \( \varphi_2 \) is a piecewise-linear quasi-interpolant of \( \varphi_h - \varphi_1 \) as defined in [2], a direct consequence of Theorem 3.1 in [2] is that there exists \( C > 0 \) such that, recalling \( \Omega_h^a := \bigcup \mathcal{T}_h^a \),
\[ \delta_1 \leq C \| \nabla (\varphi_h - \varphi_1) \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \left( \sum_{\ell \in C \setminus I_h^a} d_\ell^2 \int_{w_\ell} \varphi_{\ell}^{PU} |g - \langle g \rangle_\ell|^2 \, dx \right)^{1/2}, \]
where \( w_\ell := \text{supp}(\phi_{\ell}) \), \( \langle g \rangle_\ell := 1/|w_\ell| \int_{w_\ell} g(x) \, dx \) and \( d_\ell := \text{diam}(w_\ell) = 1 \). With the sharp Poincaré constant derived by [1], we have
\[ \int_{w_\ell} \phi_{\ell}^{PU} |g - \langle g \rangle_\ell|^2 \, dx \leq \int_{w_\ell} |g - \langle g \rangle_\ell|^2 \, dx \leq \frac{1}{4} d_\ell^2 \| \nabla g \|_{L^2(w_\ell)}^2. \]

On the other hand, \( \varphi_1 \) is a standard quasi-interpolant of \( \varphi_h \) in \( \mathcal{T}_h^c \), which implies that there exists \( C' > 0 \) such that
\[ \| \nabla (\varphi_h - \varphi_1) \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \leq C' \| \nabla \varphi_h \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)}. \] (6.5)

Due to the fact that \( d_\ell = 1 \) and that each point in \( \mathbb{R}^2 \setminus \Omega_h^a \) is covered by at most three \( w_\ell \), we have
\[ \delta_1 \leq C \max_\ell d_\ell^2 \| \nabla g \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \| \nabla \varphi_h \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \]
\[ \leq C \left( M_2 \| \nabla^2 \tilde{\dot{u}}^a \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} + M_3 \| \nabla^2 \tilde{\ddot{u}}^a \|_{L^4(\mathbb{R}^2 \setminus \Omega_h^a)} \right) \| \nabla \varphi_h \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)}, \] (6.6)
where we used the following estimate, for some \( c > 0 \),
\[ \| \nabla g \|_{L^2(\Omega_h^a)} = \| \nabla \text{div} [\partial_{\ell} W(\nabla \tilde{u}^a)] \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \]
\[ = \| \nabla (\partial_{\ell} W(\nabla \tilde{u}^a) \nabla^2 \tilde{\dot{u}}^a) \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \]
\[ = \left\| \partial_{\ell}^2 W(\nabla \tilde{\dot{u}}^a) \nabla^3 \tilde{\ddot{u}}^a + \partial_{\ell}^2 W(\nabla \tilde{u}^a) \left( \nabla^2 \tilde{\dot{u}}^a \right)^2 \right\|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} \]
\[ \leq c \left( M_2 \| \nabla^3 \tilde{\dot{u}}^a \|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)} + M_3 \| \nabla^2 \tilde{\ddot{u}}^a \|_{L^4(\mathbb{R}^2 \setminus \Omega_h^a)} \right), \]
employing the global bounds (5.7) and (5.8). This completes the estimate for \( \delta_1 \).

6.3. Estimation of \( \delta_2 \). Recall that

\[
\delta_2 := \int_{\Omega_c} (\partial_F W(\nabla \Pi_h u^a) - \partial_F W(\nabla \tilde{u}^a)) : \nabla \varphi_h.
\]

We start with estimating the best approximation error.

**Lemma 6.2.** Let \( T \in T^c_h \), \( u \in \mathcal{U}^{1,2} \) and \( v \in W^{3,2}(\mathbb{R}^2) \). Then we have the following estimates.

(a) Denote \( h_T := \text{diam}(T) \), then

\[
\| \nabla v - \nabla I_h^2 v \|_{L^2(T)} \lesssim h_T^2 \| \nabla^3 v \|_{L^2(T)}.
\]

(b) There exists a constant \( C > 0 \) such that, for any domain \( S \supset \mathcal{B}_N \),

\[
\| \nabla \mathcal{L} u - \nabla \tilde{u} \|_{L^2(S)} \leq C \| \nabla \tilde{u} \|_{L^2(S \setminus \mathcal{B}_N/2)},
\]

where \( \mathcal{L} \) is the cut-off function defined by (5.4).

(c) Furthermore, we have the best approximation error estimate

\[
\| \nabla \Pi_h u - \nabla \tilde{u} \|_{L^2(\Omega^c)} \lesssim \| h^2 \nabla^3 \tilde{u}^a \|_{L^2(\Omega^c)} + \| \nabla \tilde{u}^a \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_N/2)}
\]

\[+ N^{-1} \| h^2 \nabla^2 \tilde{u} \|_{L^2(\mathcal{B}_N \setminus \mathcal{B}_N/2)} \tag{6.7} \]

where \( h(x) := \text{diam}(T) \) with \( x \in T \).

**Proof.** Recall the uniform shape regularity assumption (2.6).

Part (a) follows directly from the Bramble–Hilbert Lemma.

For Part (b), we use a variation of Theorem 2.1 in [10]. Applying Poincaré’s inequality gives

\[
\| \nabla \mathcal{L}(u) - \nabla \tilde{u} \|_{L^2(S)} = \left\| N^{-1} \mu'(\tilde{u} - a) + (\mu - 1) \nabla \tilde{u} \right\|_{L^2(S)}
\]

\[\leq N^{-1} C_\mu \| \tilde{u} - a \|_{L^2(S)} + \| (1 - \mu) \nabla \tilde{u} \|_{L^2(S \setminus \mathcal{B}_N/2)}
\]

\[\leq C_\mu \| \nabla \tilde{u} \|_{L^2(S \setminus \mathcal{B}_N/2)}.
\]

For Part (c), we combine Part (a) and (b), that is

\[
\| \nabla \Pi_h u - \nabla \tilde{u} \|_{L^2(\Omega^c)} \lesssim \| (I_h^2 \circ \mathcal{L})(u) - \mathcal{L}(u) \|_{L^2(\Omega^c)} + \| \mathcal{L}(u) - \tilde{u} \|_{L^2(\Omega^c)}
\]

\[\lesssim \| h^2 \nabla^3 \mathcal{L}(u) \|_{L^2(\Omega^c)} + \| \nabla \tilde{u} \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_N/2)}
\]

\[= \| h^2 \sum_{n=0}^3 \frac{1}{N^n} \nabla^n \mu \nabla^{3-n}(\tilde{u} - a) \|_{L^2(\mathcal{B}_N \setminus \Omega^c)} + \| \nabla \tilde{u} \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_N/2)}
\]

\[\lesssim \| h^2 \nabla^3 \tilde{u} \|_{L^2(\Omega^c_0)} + \| \nabla \tilde{u} \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_N/2)} + \frac{1}{N} \| h^2 \nabla^2 \tilde{u} \|_{L^2(\mathcal{B}_N \setminus \mathcal{B}_N/2)}.
\]

The last line only contains the terms with \( n = 0, 1 \). The term for \( n = 2 \) is \( N^{-2} \| h^2 \nabla \tilde{u} \|_{L^2(\mathcal{B}_N \setminus \mathcal{B}_N/2)} \), but since \( N^{-2} h^2 \lesssim 1 \) this is absorbed into \( \| \nabla \tilde{u} \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_N/2)} \).

For \( n = 3 \), using Poincaré’s inequality a similar argument applies. \( \square \)
The estimate for $\delta_2$ is now a consequence of the best approximation error estimate:
\[
\delta_2 \leq \|\partial_\mathbf{t} W(\nabla \Pi_h u^a) - \partial_\mathbf{t} W(\nabla \tilde{u}^a)\|_{L^2(\Omega')} \|\nabla \varphi_h\|_{L^2(\Omega')} \\
\leq M_2 \|\nabla \Pi_h u^a - \nabla \tilde{u}^a\|_{L^2(\Omega')} \|\nabla \varphi_h\|_{L^2(\Omega')} \\
\lesssim \left( \|h^2 \nabla^3 \tilde{u}^a\|_{L^2(\Omega')} + \|h^2 \nabla \tilde{u}^a\|_{L^2(\Omega')} + N^{-1}\|h^2 \nabla^2 \tilde{u}^a\|_{L^2(\Omega')} \right) \|\nabla \varphi_h\|_{L^2(\Omega')}.
\] (6.8)

6.4. **Estimation of $\delta_3$.** Recall that
\[
\delta_3 = \int_{\Omega'} \left[ \partial_\mathbf{t} W(\nabla \tilde{u}^a) - \partial_\mathbf{t} W(\nabla u^a) \right] : \nabla \varphi,
\]
where $\varphi$ is a lattice function with compact support and $\nabla \varphi$ denotes the gradient of its piecewise linear interpolant. To estimate this term we observe that $u^a$ can be interpreted as the $P_1$ nodal interpolant of $\tilde{u}^a$. Although this indicates a first-order estimate only, we can exploit mesh regularity to obtain a second-order superconvergence estimate.

To that end, we rewrite the integral over the domain as a summation of elements. Let $\hat{E}$ be the union of edges that are shared by two continuum elements, and $\omega_e$ be the union of said elements, i.e.,
\[
\hat{E} : = \{ e = T_1 \cap T_2 \mid T_1, T_2 \in \mathcal{T}_c \} \\
\omega_e : = T_1 \cup T_2, \text{ where } T_1 \cap T_2 = e.
\]

Recall that $W(F) \equiv \frac{1}{\Omega_0} V(F \cdot a)$. Observe that for a pair of $T_1, T_2$ sharing a common edge $e$ which has the direction of $a_j$, $\nabla_{a_j} \varphi(T_1) = \nabla_{a_j} \varphi(T_2)$, which allows us to re-group integration over elements as integration of patches $\omega_e$ except for elements near the interface. After simplifying the notation by writing $\hat{V}_j : = \partial_\mathbf{t} V(\nabla \tilde{u} \cdot a)$ and $V_j : = \partial_\mathbf{t} V(\nabla u \cdot a)$, we can rewrite $\delta_3$ as follows:
\[
\delta_3 = \frac{1}{\Omega_0} \sum_{T \in \mathcal{T}_c \cup \mathcal{T}_z} \sum_{j=1}^6 \int_{T \cap \Omega'} [\hat{V}_j - V_j] \cdot \nabla_{a_j} \varphi(T) \\
= \frac{1}{\Omega_0} \sum_{j=1}^6 \sum_{e \in \omega_j} \int_{\omega_e} [\hat{V}_j - V_j] \cdot \nabla_{a_j} \varphi \\
+ \frac{1}{\Omega_0} \sum_{T \in \mathcal{T}_c \cup \mathcal{T}_z} \sum_{j=1}^6 c_{T,j} \int_{T \cap \Omega'} [\hat{V}_j - V_j] \cdot \nabla_{a_j} \varphi(T) \\
=: \tau_1 + \tau_2,
\]
where $\hat{E}_j : = \{ e \in \hat{E} \mid e \text{ is in the direction of } a_j \}$ and $c_{T,j}$ is defined as follows,
\[
c_{T,j} = \begin{cases} 
0, & \exists e \in \hat{E}_j \cap T, \\
1, & \text{otherwise}.
\end{cases}
\]

Observe that for $T \in \mathcal{T}_c$, $c_{T,j}$ is only non-zero near the interface. So we have
\[
\tau_2 \leq \frac{1}{\Omega_0} \int_{\Omega'_+} M_2 |\nabla \tilde{u}^a - \nabla u^a| |\nabla \varphi| \lesssim \|\nabla^2 \tilde{u}^a\|_{L^2(\Omega'_+)} \|\nabla \varphi\|_{L^2(\Omega'_+)},
\] (6.9)
where $\Omega^i_+ := \bigcup \{ T \in T_C \mid \text{dist}(T, \Omega^i) \leq 1/2\}$. Note that the second-order error $\nabla^2 \tilde{u}^a$ results from the fact that $u^a$ is a piecewise linear nodal interpolant of $\tilde{u}^a$ on a uniform mesh.

To estimate $\tau_1$, we employ the following second-order mid-point estimate.

**Lemma 6.3.** Suppose $f \in W^{2,\infty}(T_1 \cup T_2; \mathbb{R})$ where $T_1, T_2 \in T$ such that they share an edge $e$ and let $m_e$ be the mid-point of $e$, then

$$
\left| \int_{T_1 \cup T_2} f(\xi) - f(m_e) \, d\xi \right| \lesssim \| \nabla^2 f \|_{L^\infty(T_1 \cup T_2)}.
$$

Then we can write

$$
\tau_1 = \frac{1}{\Omega_0} \sum_{j=1}^6 \sum_{e \in E_j} \int_{\omega_e} \left[ (\tilde{V}_j - \tilde{V}_j(m_e)) - (V_j - \tilde{V}_j(m_e)) \right] \cdot \nabla a_j \varphi.
$$

(6.10)

By Lemma 6.3 we have

$$
\left| \int_{\omega_e} (\tilde{V}_j - \tilde{V}_j(m_e)) \right| \lesssim \| \nabla^2 \partial_j V(\nabla \tilde{u}^a \cdot a) \|_{L^\infty(\omega_e)}
\lesssim (M_3 \| \nabla^2 \tilde{u}^a \|_{L^\infty(\omega_e)}^2 + M_2 \| \nabla^3 \tilde{u}^a \|_{L^\infty(\omega_e)})
\lesssim \| \nabla^2 \tilde{u}^a \|_{L^2(\omega_e)}^2 + \| \nabla^3 \tilde{u}^a \|_{L^2(\omega_e)},
$$

(6.11)

where the last line comes from the fact that $\tilde{u}^a$ is a polynomial of degree 5 on each $T$, hence on each patch $\omega_e$ the norms are equivalent.

On the other hand, for $i = 1, \ldots, 6$ we denote $\nu_{T,i}$ and $\nu_{T,i'}$ as the vertices of $T$ with $\nu_{T,i} + a_i = \nu_{T,i'}$. Then on $T \supset e$, we have, using Taylor expansion,

$$
\nabla u^a \big|_T \cdot a_i - \nabla \tilde{u}^a(m_e) \cdot a_i = \tilde{u}^a(\nu_{T,i'}) - \tilde{u}^a(\nu_{T,i}) - \nabla \tilde{u}^a(m_e) \cdot a_i = \tau_e,
$$

where $|\tau_e| \lesssim \| \nabla^3 \tilde{u}^a \|_{L^\infty(\omega_e)}$. Then for $T_1$ and $T_2$ with $T_1 \cap T_2 = e = [\nu_{T,i}, \nu_{T,i'}]$, we have

$$
[\nabla u^a(T_1) \cdot a_i - \nabla \tilde{u}^a(m_e) \cdot a_i] + [\nabla u^a(T_2) \cdot a_i - \nabla \tilde{u}^a(m_e) \cdot a_i] = 2\tau_e.
$$

(See also Figure 10.) Hence, we can estimate
\[ \left| \int_{\omega_e} V_j - \tilde{V}_j(m_e) \right| = \left| T_1 \right| (V_j|T_1 - \tilde{V}_j(m_e)) + \left| T_2 \right| (V_j|T_2 - \tilde{V}_j(m_e)) = |T_1| \sum_{i=1}^{6} \partial_{j,i} V(\nabla \tilde{u}^a(m_e) \cdot a) \left[ \nabla u^a|T_1 \cdot a_i - \nabla \tilde{u}^a(m_e) \cdot a_i + \nabla u^a|T_2 \cdot a_i - \nabla \tilde{u}^a(m_e) \cdot a_i \right] + O(M_3 \| \nabla^2 \tilde{u}^a \|^2_{L^\infty(\omega_e)}) \leq M_2 \| \nabla^3 \tilde{u}^a \|_{L^\infty(\omega_e)} + M_3 \| \nabla^2 \tilde{u}^a \|^2_{L^\infty(\omega_e)}.\]

Combining this estimate with (6.11), we have
\[ \tau_1 \lesssim \left\{ \| \nabla^2 \tilde{u}^a \|^2_{L^2(\Omega_e^\mathcal{C})} + \| \nabla^3 \tilde{u}^a \|_{L^2(\Omega_e^\mathcal{C})} \right\} \| \nabla \varphi \|_{L^2(\Omega_e^\mathcal{C})}.\]

Finally, combining the last estimate with (6.9) we obtain
\[ \delta_3 \lesssim \left\{ \| \nabla^2 \tilde{u}^a \|^2_{L^2(\Omega_e^\mathcal{C})} + \| \nabla^2 \tilde{u}^a \|^2_{L^2(\Omega_e^\mathcal{C})} + \| \nabla^3 \tilde{u}^a \|_{L^2(\Omega_e^\mathcal{C})} \right\} \| \nabla \varphi \|_{L^2(\Omega_e^\mathcal{C})}. \tag{6.12} \]

6.5. Estimation of $\delta_4$. We observe that $\delta_4$ requires the estimation of pure modelling errors regardless of the choice of finite element approximation or domain truncation. This term was the main focus of [12], where the following result was proven.

**Theorem 6.4 (Theorem 5.1 [12]).** Let $u : \Lambda \to \mathbb{R}^m$ and let $\varphi : \Lambda \to \mathbb{R}^m$ with compact support, then
\[ \langle \delta \mathcal{E}^{23}(u^a) - \delta \mathcal{E}^a(u^a), \varphi \rangle \lesssim \left( M_2 \| D^2 u^a \|_{L^2(\sigma)} + M_2 \| D^3 u^a \|_{L^2(\sigma)} + M_3 \| D^2 u^a \|_{L^2(\sigma)} \right) \| D \varphi \|_{L^2(\Lambda \setminus A)}, \]

where $\sigma^\mathcal{C} := \{ \ell \in \Lambda | \text{dist}(\ell, \mathcal{I}) \leq 1 \}$.

By the construction of the smooth interpolant $\tilde{u}$ in Lemma 6.1 we therefore conclude that
\[ \delta_4 \lesssim \left( \| \nabla^2 \tilde{u}^a \|^2_{L^2(\Omega_e^\mathcal{C})} + \| \nabla^3 \tilde{u}^a \|_{L^2(\Omega_e^\mathcal{C})} + \| \nabla^2 \tilde{u}^a \|^2_{L^2(\Omega_e^\mathcal{C})} \right) \| \nabla \varphi \|_{L^2(\Omega_e^\mathcal{C})}. \tag{6.13} \]

6.6. Proof of Theorem 3.2. Recall from (6.1) the splitting of the consistency error into $\eta_{\text{ext}}$ and $\eta_{\text{int}}$. From the definition of $\varphi$ in (6.4) it follows that $\eta_{\text{ext}} = 0$.

In (6.2) the term $\eta_{\text{int}}$ is further split into $\delta_1, \ldots, \delta_4$ which are respectively estimated in (6.6), (6.8), (6.12) and (6.13). Combining these four estimates, the stated result (3.3) follows.

6.7. Proof of the estimate (3.5). A key aspect of our analysis is the optimisation of the approximation parameters: First, we determine a mesh size $h$ so that the finite element error is balanced with the modelling error. Secondly, the domain radius $N$ and the atomistic radius $K$ will be balanced. Finally, in order to compare the efficiency against different methods, we will express the convergence rate of the total error in terms of numbers of degree of freedom only.
We first estimate the decay rate of each term in the consistency estimate (3.3). Recall that Corollary 3.1 implies $|\nabla^j \tilde{u}^a(x)| \lesssim |x|^{-1-j}$. Hence, we can estimate the interface error by

$$
\|\nabla^2 \tilde{u}^a\|_{L^2(\Omega)} \lesssim \left( \int_{\Omega} |x|^{-6} \right)^{1/2} \lesssim (K \cdot K^{-6})^{1/2} \lesssim K^{-5/2}.
$$

(6.14)

Similarly, we have

$$
\|\nabla^3 \tilde{u}^a\|_{L^2(\Omega)} \lesssim \left( \int_{\Omega} |x|^{-8} dx \right)^{1/2} \lesssim \left( \int_{K}^{\infty} r^{-8} dr \right)^{1/2} \lesssim K^{-3},
$$

$$
\|\nabla^2 \tilde{u}^a\|_{L^4(\Omega)} \lesssim \left( \int_{\Omega} |x|^{-12} dx \right)^{1/2} \lesssim \left( \int_{K}^{\infty} r^{-12} dr \right)^{1/2} \lesssim K^{-5},
$$

$$
\|\nabla \tilde{u}^a\|_{L^2(\Omega \setminus B_{N/2})} \lesssim \left( \int_{\Omega \setminus B_{N/2}} |x|^{-4} dx \right)^{1/2} \lesssim \left( \int_{N/2}^{\infty} r^{-4} dr \right)^{1/2} \lesssim N^{-1}.
$$

(6.15)

We observe that the interface term (6.14) dominates the consistency error. Balancing this with the far-field term (6.15) gives

$$
N^{-1} \approx K^{-5/2}, \quad \text{i.e.,} \quad N \approx K^{5/2}.
$$

To determine the mesh size $h$, we write $h(x) := \left( \frac{|x|}{K} \right)^{\beta}$. Then we have

$$
\|h^2 \nabla^3 \tilde{u}^a\|_{L^2(\Omega)} \lesssim \left( \int_{\Omega} \frac{|x|^{4\beta}}{K^{4\beta}} |x|^{-8} dx \right)^{1/2}
$$

$$
= \frac{1}{K^{2\beta}} \left( \int_{K}^{N} r^{-1+4\beta-8} dr \right)^{1/2}
$$

$$
= \frac{1}{K^{2\beta}} \left( \frac{x^{4\beta-6}}{r=K} \right)^{1/2}
$$

$$
\approx K^{-3}, \quad \text{provided that} \ 4\beta - 6 < 0.
$$

The final remaining term is

$$
N^{-1} \|h^2 \nabla^2 \tilde{u}^a\|_{L^2(\Omega \setminus B_{N/2})} \lesssim N^{-1} \left( \int_{\Omega \setminus B_{N/2}} \frac{|x|^{4\beta}}{K^{4\beta}} |x|^{-6} dx \right)^{1/2}
$$

$$
\lesssim N^{2\beta-3} K^{-2\beta} \lesssim K^{3\beta-\frac{15}{2}}.
$$

Since we chose $\beta < 3/2$, it follows that $K^{-3}$ dominates $K^{3\beta-\frac{15}{2}}$.

Therefore, the error rate for the optimal finite element coarsening is $K^{-3}$ and to attain it we must choose

$$
h(x) \approx \left( \frac{|x|}{K} \right)^{\beta}, \quad \text{where} \ \beta < \frac{3}{2}.
$$

Finally, we estimate the relationship between the number of degrees of freedom $N_h$ and the atomistic radius $K$. It is easy to see that the number of degrees of freedom in the atomistic domain satisfies $N_a \approx K^2$. Next, one can estimate the degrees of freedom in the continuum domain $N_c$ by considering each hexagonal layer of the
mesh. On each layer with radius \( r \), \( N_{\text{layer}} \approx r \frac{r}{h(r)} \). Summing over all layers in the continuum region gives

\[
N_c \approx \sum_{\text{layers in } \Omega_c} \left( \frac{h}{h} \right)^2 \frac{r}{h} \\
\approx \int_K^N \frac{r}{h(r)^2} dr \\
\approx \int_K^N r^{1-2\beta} K^{2\beta} dr \\
\approx (-N^{2-2\beta} + K^{2-2\beta}) K^{2\beta}, \quad \text{provided that } 2 - 2\beta < 0, \\
\approx K^2.
\]

Therefore, we deduce that the mesh grading should satisfy \( 1 < \beta < \frac{3}{2} \) to obtain the optimal cost/accuracy ratio for the error in the energy-norm, \( K^{-5/2} \approx N_h^{-5/4} \). The table in § 3.3.2 summarises the derivation of this section.

### 7. Proof of Theorem 3.4

#### 7.1. Existence and error in energy norm

We refer to the inverse function theorem, Theorem 5.1. Let \( \delta \mathcal{G}_h := \delta \mathcal{E}^{23} - \delta f \) and \( \bar{u}_h := \Pi_h u^a \). We have already shown in Theorem 3.2 and Lemma 5.4 that

\[
\| \mathcal{G}_h(\bar{u}_h) \|_{U_h} \leq \eta, \\
\langle \delta \mathcal{G}_h(\bar{u}_h), v_h \rangle \geq \gamma \| \nabla v_h \|_{L^2}^2 \quad \text{for all } v_h \in U_h,
\]

with \( \eta = \eta_{\text{int}} + \eta_{\text{ext}} \) and

\[
\eta_{\text{int}} \lesssim \| \nabla^2 \bar{u}^a \|_{L^2(\Omega)} + \| \nabla^3 \bar{u}^a \|_{L^2(\Omega')} + \| \nabla^2 \bar{u}^a \|_{L^4(\Omega')} + \| h^2 \nabla^2 \bar{u}^a \|_{L^2(\Omega')} + \| \nabla \bar{u}^a \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{R_N})} + N^{-1} \| h^2 \nabla \bar{u}^a \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{R_N})}
\lesssim N_h^{-5/4}.
\]

For \( \eta_{\text{ext}} \), recall that \( \partial u(\ell) f(u) = 0 \) for all \( |\ell| \geq R_f \), and that \( K \geq R_f \). We have, on \( \text{supp}(\partial u(\ell) f(u)) \), \( \nabla \Pi_h u^a = \nabla u^a \) and \( \nabla \varphi_h = \nabla \varphi \). Thus \( \eta_{\text{ext}} = 0 \) and

\[
\eta = \eta_{\text{int}} \lesssim N_h^{-5/4}.
\]

Using also the Lipschitz bound from Lemma 5.3 Theorem 5.1 implies, for \( K \) sufficiently large, that there exists a strongly stable minimizer \( u^{23}_h \in U_h \) such that

\[
\langle \delta \mathcal{E}^{23}(u^{23}_h), \varphi_h \rangle - \langle \delta f(u^{23}_h), \varphi_h \rangle = 0, \quad \forall \varphi_h \in U_h,
\]

and

\[
\| \nabla u^{23}_h - \nabla \Pi_h u^a \|_{L^2} \leq 2 \frac{\eta}{\gamma} \\
\lesssim \| \nabla^2 \bar{u}^a \|_{L^2(\Omega)} + \| \nabla^3 \bar{u}^a \|_{L^2(\Omega')} + \| \nabla^2 \bar{u}^a \|_{L^4(\Omega')} + \| h^2 \nabla^2 \bar{u}^a \|_{L^2(\Omega')} + \| \nabla \bar{u}^a \|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{R_N})}
\lesssim N_h^{-5/4}.
\]
Adding the best approximation error (6.7) gives
\[
\|\nabla u_h^{g23} - \nabla u^a\|_{L^2} \leq \|\nabla u_h^{g23} - \nabla \Pi_h u^a\|_{L^2} + \|\nabla \Pi_h u^a - \nabla u^a\|_{L^2} \\
\lesssim \mathcal{N}_h^{-5/4} + \|h^2 \nabla^3 \tilde{u}\|_{L^2(\mathbb{T}_h^a)} + \|\nabla \tilde{u}\|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{N/2})} \\
\lesssim \mathcal{N}_h^{-5/4}.
\]
This completes the proof of Theorem 3.4.

7.2. The energy error. In this section we prove the energy error estimates stated in Theorem 3.4. For the sake of notational simplicity we define \(E^a_f := E^a - f\) and \(E^{g23}_f := E^{g23} - f\).

First, we observe that
\[
|E^{g23}_f(u_h^{g23}) - E_f^a(u^a)| \leq |E^{g23}_f(u_h^{g23}) - E^{g23}_f(\Pi_h u^a)| + |E^{g23}_f(\Pi_h u^a) - E_f^a(u^a)|
=: e_1 + e_2.
\]
The first term can be estimated by (3.6) and the fact that \(\langle \delta E^{g23}_f(u_h^{g23}), \varphi_h \rangle = 0\) for all \(\varphi_h \in \mathcal{U}_h\):
\[
e_1 \leq \left| \langle \delta E^{g23}_f(u_h^{g23}), \Pi_h u^a - u_h^{g23} \rangle \right|
+ \left| \int_0^1 (1-t) \langle \delta^2 E^{g23}_f(u_h^{g23} + t(\Pi_h u^a - u_h^{g23})), (\Pi_h u^a - u_h^{g23}) \rangle dt \right|
\lesssim \|\nabla \Pi_h u^a - \nabla u_h^{g23}\|_{L^2} \lesssim K^{-5} \lesssim \mathcal{N}_h^{-5/2}.
\]
(7.1)
For the second term we use the fact that \(E^{g23}_f(0) = E^a(0)\), and hence \(E^{g23}_f(0) = E_f^a(0)\), to estimate
\[
e_2 \leq |E^{g23}_f(0) - E_f^a(0)| + \left| \int_0^1 \langle \delta E^{g23}_f(t(\Pi_h u^a), \Pi_h u^a) \rangle dt - \int_0^1 \langle \delta E^a_f(t u^a), u^a \rangle dt \right|
\leq \left| \int_0^1 \langle \delta E^{g23}_f(t(\Pi_h u^a), \Pi_h u^a) - \delta E^a_f(t u^a), v \rangle dt \right|
+ \left| \int_0^1 \langle \delta E^a_f(t u^a), u^a \rangle dt \right|
=: e_{21} + e_{22},
\]
where \(v : \Lambda \to \mathbb{R}^m\) is an arbitrary test function.

7.2.1. Estimate for \(e_{21}\). To exploit the consistency error estimate we choose \(v := \Pi_h^* \Pi_h u^a\) defined in (6.4). In this case, similar to estimating \(\eta_{nat}\), we obtain
\[
e_{21} \lesssim \int_0^1 \hat{\eta}_{nat}(t) dt \|\nabla \Pi_h u^a\|_{L^2(\mathbb{R}^2 \setminus \Omega_h^a)}
\]
where
\[
\hat{\eta}_{nat}(t) = \|\nabla^2 \tilde{u}^a\|_{L^2(\Omega)} + \|\nabla^3 \tilde{u}^a\|_{L^2(\Omega')} + \|\nabla^2 \tilde{t} \tilde{u}^a\|_{L^2(\Omega')} + \|h^2 \nabla^3 \tilde{t} \tilde{u}^a\|_{L^2(\Omega_h^a)}
+ \|\nabla \tilde{u}^a\|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{N/2})} + N^{-1} \|h^2 \nabla^2 \tilde{t} \tilde{u}\|_{L^2(\mathbb{R}^2 \setminus \mathcal{B}_{N/2})}
\lesssim tK^{-5/2}.
\]
From Corollary 3.1 and 6.2 it follows that \(\|\nabla \Pi_h u^a(x)\| \lesssim |x|^{-2}\) hence we can deduce that
\[
e_{21} \lesssim K^{-5/2} K^{-1} = K^{-7/2} \lesssim \mathcal{N}_h^{-7/4}.
\]
(7.2)
7.2.2. Estimate for $e_{22}$. First we observe that by Trapezoidal rule, if $\zeta \in C^2(\mathbb{R})$ and $\zeta(0) = \zeta(1) = 0$, then we have for some $\theta \in [0, 1]$,
\[
\int_0^1 \zeta(t) \, dt = -\frac{1}{12} \zeta''(\theta).
\]
Let $\zeta(t) := \langle \delta \mathcal{E}_f^a(tu^a), v - u^a \rangle$. Then $\zeta(1) = 0$ since $\delta \mathcal{E}_f^a(u^a) = 0$ and $\zeta(0) = 0$ since $\delta \mathcal{E}^a(0) = 0$ and $\partial u(\ell) f(u) = 0$ outside defect core while $v = u^a$ in the defect core.

Having $e_{22} = \int_0^1 \zeta(t) \, dt$ we obtain
\[
e_{22} \lesssim \delta^3 \mathcal{E}^a(\theta u^a)[u^a, u^a, v - u^a]
\lesssim M_3 \sum_{\ell \in \mathcal{A} \setminus \Lambda} |Du^a(\ell)|^2 |Dv(\ell) - Du^a(\ell)|
\lesssim \int_{R^2 \setminus \Omega^a} |\nabla \tilde{u}^a|^2 |\nabla v - \nabla u^a|,
\]
where we recall that $v := \Pi_h \Pi_k u^a$. Using the stability (6.5) we obtain
\[
e_{22} \lesssim \|\nabla \tilde{u}^a\|_{L^2(R^2 \setminus \Omega^a)}^2 + \|\nabla \tilde{u}^a\|_{L^2(R^2 \setminus \Omega^a)}^2 \|\nabla \Pi_k u^a\|_{L^2(R^2 \setminus \Omega^a)}
\lesssim \int_K rr^{-6} \, dr + \left( \int_K rr^{-8} \, dr \right)^{1/2} \left( \int_K rr^{-4} \, dr \right)^{1/2}
\lesssim K^{-4} + K^{-3} K^{-1} = K^{-4}.
\]

Combining (7.1), (7.2) and (7.3) completes the proof of the energy error estimate (3.7) and therefore of our main result, Theorem 3.4.
