1  
2  
3 *Daucus* traditionally has been estimated to contain 21–25 species, but a  
4 recent study expanded the genus to contain about 40 species. The present  
5 study uses ten nuclear orthologs to examine 125 accessions, including 40  
6 collections of eleven species newly examined with nuclear orthologs: *D.*  
7 *annuus*, *D. arcanus*, *D. decipiens*, *D. durieua*, *D. edulis*, *D. gracilis*, *D.*  
8 *minusculus*, *D. montanus*, *D. pumilus*, *D. setifolius*, and *D. tenuissimus*. As in  
9 prior nuclear ortholog studies, *Daucus* resolves into two well-defined clades,  
10 and groups different accessions of species together. Maximum likelihood and  
11 maximum parsimony analyses provide concordant results but SVD quartets (a  
12 species tree approach) has many areas of disagreement of species within these  
13 two major clades. Maximum likelihood and maximum parsimony analyses resolve  
14 *Daucus montanus* (hexaploid) as an allopolyploid between *D. pusillus* (diploid)  
15 and *D. glochidiatus* (tetraploid) and SVD quartets as an allopolyploid between  
16 *D. glochidiatus* and an unknown *Daucus* species. We propose the new combination  
17 *Daucus junceus* (*Durieua juncea*) for a neglected species endemic to SW Iberian  
18 Peninsula often referred to as *D. setifolius*, and place *D. arcanus* in  
19 synonymy with *D. pusillus*. Three lectotypes are also designated.

## INTRODUCTION

The latest comprehensive taxonomic monograph of *Daucus* L. by Sáenz (1981) recognized 21 species; Rubatzky, Quirós & Simon (1999) later estimated 25 species. Recent morphological and molecular studies using a variety of plastid and nuclear DNA sequences have been drastically changing our understanding of the species boundaries (Arbizu *et al.*, 2014b, 2016; Spooner *et al.*, 2014), and ingroup and outgroup relationships of *Daucus* (e.g., Spalik & Downie, 2007; Arbizu *et al.*, 2014a; Banasiak *et al.*, 2016; Spooner *et al.*, 2017). Banasiak *et al.* (2016) used DNA sequences from nuclear ribosomal ITS and the three plastid markers (*rps16* intron, *rpoC1* intron, and *rpoB-trnC* intergenic spacer) to redefine and expand the genus *Daucus* to include the following genera and species into its synonymy: *Agrocharis* Hochst. (4 species), *Melanoselinum* Hoffm. (1 species), *Monizia* Lowe (1 species), *Pachyctenium* Maire & Pamp. (1 species), *Pseudorlaya* (Murb.) Murb. (2 species), *Rouya* Coincy (1 species), *Tornabenea* Parl. (6 species), *Athamanta della-cellae* Asch. & Barbey ex E.A.Durand & Barratte, and *Cryptotaenia elegans* Webb ex Bolle. They made the relevant nomenclatural transfers into *Daucus*, expanding the genus to contain about 40 species. In addition, they divided *Daucus* into four sections, three of which (section *Daucus*, section *Melanoselinum* (Hoffm.) Spalik *et al.*, section *Anisactis* DC) we examine here, not examining section *Agrocharis* (Hochst) Spalik *et al.* that is sister to the sections above and comprised of the former genus *Agrocharis* Hochst. This expansion of *Daucus* and new sectional classification renders *Daucus* quite difficult to characterize morphologically, and was based solely on molecular data.

Arbizu *et al.* (2014a) identified 94 nuclear orthologs in *Daucus*, constructed a phylogenetic tree with these, and determined ten of them to

provide essentially the same result as all 94, paving the way for additional cost-effective nuclear ortholog studies in carrot. These ten nuclear orthologs were then successfully used in a focused study of the species boundaries of the *D. guttatus* Sibth. & Sm. complex (Arbizu et al., 2016), which, in concert with data from type specimens (Martínez-Flores et al., 2016), redefined the species boundaries and nomenclature of this group. The focus of the present study is to expand further these studies by adding 40 accessions of taxa from eleven species and from areas not examined with these ten nuclear orthologs. We provide suggestions on further taxonomic research on *Daucus*, and new taxonomic decisions and synonymies (below).

## MATERIALS AND METHODS

### ACCESSIONS EXAMINED

Previously sequenced amplicons were obtained from Arbizu et al. (2014a, 2016), and are listed in those publications. The 40 new accessions (Table 1) were obtained from (1) the Agrocampus Ouest - IRHS, France, (2) the Warwick Crop Centre, UK, and (3) an expedition in Spain in 2016. Newly examined taxa are *D. annuus* (Bég.) Wojew. et al. ≡ *Tornabenea annua* Bég., *D. arcanus* García Martín & Silvestre, *D. decipiens* (Schrad. & J.C.Wendl.) Spalik et al. ≡ *Melanoselinum decipiens* (Schrad. & J.C.Wendl.) Hoffm., *D. durieua* Lange, *D. edulis* (Lowe) Wojew. et al. ≡ *Monizia edulis* Lowe, *D. gracilis* Steinh., *D. minusculus* Pau ex Font Quer ≡ *Pseudorlaya minuscula* (Pau ex Font Quer) M.Lainz, *D. montanus* Humb. & Bonpl. ex Schult., *D. pumilus* (L.) Hoffmanns. & Link ≡ *Pseudorlaya pumila* (L.) Grande, *D. setifolius* Desf., and *D. tenuissimus* (A.Chev.) Spalik et al. ≡ *Tornabenea tenuissima* (A.Chev.) A.Hansen & Sunding. We lack vouchers for three accessions that grew as young plants sufficient to obtain DNA, but failed to grow to flowering stage as is typical for some

1  
2  
3 species of *Daucus* that are biennials or have other problems flowering in  
4 cultivation.  
5  
6

7 CHROMOSOME COUNTS  
8

9 We obtained chromosome counts of all the species examined in this study from  
10 the literature using the Missouri Botanical Garden Index to Plant Chromosome  
11 Numbers (IPCN; Goldblatt & Johnson, 1979--;  
12  
<https://www.tropicos.org/Project/IPCN> (Table 2) and other sources from the  
13  
14 *Daucus* literature. We found chromosome number references for all examined  
15 species except for *Daucus bicolor*, *Daucus conchitae* and *Daucus gracilis*.

23 DNA EXTRACTION AND SEQUENCE GENERATION  
24

25 New accessions were grown a greenhouse at the University of Wisconsin-  
26 Madison, tissue harvested and freeze-dried leaves, and DNA extracted with  
27 CTAB (Doyle & Doyle, 1990). For markers dc10366, dc10966, dc15347, dc16308,  
28 dc16577, dc3374, dc3902, and dc35097, 200 ng of DNA was amplified in 20 µL  
29 volume containing 1X Buffer, 1.5 mM MgCl<sub>2</sub>, 0.2 mM dNTP (Promega Corporation,  
30 USA), 0.2 µM each forward and reverse primer, and 1 U taq (GoTaq®, Promega  
31 Corporation, USA) with the following program steps of 94°C for 5 minutes, 35  
32 cycles of 94°C for 30 seconds, 55°C for 1 minute, and 72°C for 2 minutes,  
33 followed by 72°C for 10 minutes. For markers dc16645 and dc32914, and any  
34 unamplified product from the previous eight markers, the magnesium  
35 concentration was doubled to 3 mM and the annealing step lowered from 55°C to  
36 50°C. The forward and reverse strands were Sanger sequenced for each amplicon  
37 at the Biotechnology Center of the University of Wisconsin-Madison. Amplicons  
38 SNP differences or with an insertion or deletion, discovered during Sanger  
39 sequencing, were further processed with SSCP following Cai et al. (2012),  
40 using the MDE gel solution and 72 hr run times.

56 PHYLOGENETIC ANALYSES  
57  
58  
59  
60

We deposited all sequences in GenBank (Supplementary file 1); sequences were assembled with PreGap4 and Gap4 (Staden, 1996), aligned with MUSCLE version 3.8.31 (Edgar, 2004), and alignments corrected in Mesquite version 3.31 (Maddison & Maddison, 2017). A major analytical problem, most critical for analyses with multiple and highly unlinked nuclear orthologs is how to align allelic data across markers data in concatenated analyses. There is no logical solution to concatenate such widely dispersed ortholog data unambiguously. We addressed this challenge by separating the alleles into two randomly chosen sets in concatenated matrices and examining each of these two datasets separately. As detailed below, maximum likelihood (ML) and maximum parsimony (MP) results were unambiguous in showing that the two analyses positioned all 124 accessions in nearly equal positions on the tree, except for the allopolyploid *Daucus montanus*, that in one set resolved with *D. durieua* and in the other set with *D. glochidiatus*. Based on this result we analyzed each of the 20 ortholog trees separately (10 for set A and 10 for set B) and these individual analyses clearly showed the orthologs supporting an allopolyploid origin from *D. durieua* and *D. glochidiatus*. Only when *D. montanus* is included do we find internal conflict of A and B allele sets.

The aligned file A (see below) is deposited in TreeBASE (submission ID 32618). We rooted our trees on *Athamanta sicula* based on Downie, Katz-Downie & Spalik (2000). Maximum parsimony analysis was conducted in PAUP\* version 4.0a145 (Swofford, 2002). Missing data and gaps were all scored as missing data. All characters were treated as unordered and weighted equally (Fitch, 1971). The most parsimonious trees were found using a heuristic search (Farris, 1970) by generating 100,000 random taxon addition sequence replicates using tree-bisection reconnection (TBR) and holding one tree for each replicate. Then, we ran a final heuristic search of the most equally parsimonious trees from this analysis using TBR and MULPARS. Bootstrap values

(Felsenstein, 1985) for the clades were estimated using 1,000 replicates with a heuristic search, TBR and MULPARS, setting MAXTREES to 1000.

Maximum likelihood analysis was conducted via the CIPRES (Miller, Pfeiffer & Schwartz, 2010) portal at the San Diego Supercomputer Center (<http://www.phylo.org>) with the GTR + G nucleotide substitution model using RAxML version 8.2.4 (Stamatakis, 2014). The most common model of evolution for DNA analysis is general time-reversible (GTR) (Summer *et al.*, 2012) being the main reason only GTR-based models are implemented in RAxML (Stamatakis, 2014). We obtained the best-scoring ML tree from 100 independent ML tree searches, and then 1,000 nonparametric bootstrap inferences were performed with the same program. As in MP, we rooted our tree on *Athamanta sicula*.

We also conducted a singular-value decomposition (SVD) quartets analysis using the multispecies coalescent option (Chifman & Kubatko, 2014, 2015) (a species tree approach) with 100 bootstrap replicates, also using PAUP\* version 4.0a131.

## RESULTS

### MAXIMUM PARSIMONY

The number of alleles for the ten nuclear orthologs of our new data varied from 1-2. Some failed to amplify, with an average of 9.2% missing data across all markers (Supplementary file 2). Tree statistics for the four main analyses under MP (A allele and B allele, each with and without *D. montanus*) are presented in Supplementary file 3. The MP A (Supplementary file 4) and B set (Fig. 1) trees were extremely similar, except for *D. montanus* that in one set resolved in a clade with *D. pusillus* Michx., and in another with *D. glochidiatus* (Labill.) Fisch., C.A.Mey. & Avé-Lall. Hence, we examined each of the ten genes separately for each set, with and without *D. montanus* (20 analyses in total), and found that the alleles of *D. montanus* resolved into

different species (Supplementary file 5; Table 3), supporting an allopolyploid origin between *D. pusillus* and *D. glochidiatus*.

Figure 1 is of the B set run without *D. montanus*, which was then added manually relative to *D. pusillus* and *D. glochidiatus*. Relative to prior studies using these markers, *Daucus* resolves into two well-defined clades A and B, and the species with 2n=18 chromosomes into subclade A' (except for *D. tenuissimus*, 2n = 16). The newly examined taxa resolve in clade B as *D. arcanus* sister to *D. pusillus* and *D. durieua* sister to *D. glochidiatus*. In clade A, *D. annuus*, *D. gracilis*, and *D. tenuissimus* resolve into clade A'; *D. decipiens*, *D. edulis*, *D. minusculus*, and *D. pumilus* (along with previously examined *D. rouyi*) sister to clade A'; and *D. setifolius* sister to *D. crinitus*. *Daucus montanus* (a hexaploid) is an apparent allopolyploid between *D. pusillus* (diploid) and *D. glochidiatus* (tetraploid). These results partly match the new sectional classification of Banasiak et al. (2016) except that the Macronesian endemic species *D. decipiens* and *D. edulis* are embedded in clade A (their section *Daucus*), not as a separate basal clade to clade A that they recognize as section *Melanoselinum*. The remaining species of clade B match the placement of their section *Anisactis*, yet not with the same cladistic structure within these clades.

Figure 1 shows the chromosome numbers (Table 2) supporting clades. In some cases, there is chromosome number support for clades, for example *Daucus arcanus* and *D. pusillus* or *D. aureus* and *D. muricatus*. In many other cases, there is poor association of chromosome numbers and clades.

#### MAXIMUM LIKELIHOOD

The ML tree of allele set B is presented in Supplementary file 6. Except for minor differences in the topology of some duplicate accessions within species exhibiting low bootstrap values in both ML and MP analyses (e.g., *D. conchitae*, *D. guttatus*), and in the topology of *D. aureus* and *D. muricatus*,

1  
2  
3 there are no substantive differences between the ML and MP analyses. In the  
4 MP analysis *D. aureus* and *D. muricatus* are sister taxa with moderate (77%)  
5 bootstrap support, but in the ML analysis *D. muricatus* is sister to a clade  
6 containing *D. aureus*, other members of the A' clade, *D. rouyi*, *D. minusculus*  
7 and *D. pumilus*.  
8  
9  
10  
11

12  
13  
14 SVD QUARTETS MULTISPECIES COALESCENT ANALYSIS  
15

16 As molecular systematics progressed, multiple datasets using different genes  
17 or gene regions for the same accessions became common. It was soon discovered  
18 that the results typically showed some incongruence, and were sometimes very  
19 incongruent (Wendel & Doyle, 1998; Rokas et al., 2003). A number of solutions  
20 were advanced for this problem, one a total evidence analysis of a single  
21 concatenated dataset, which essentially joins all of the independent data  
22 together as a single locus to resemble one large supergene (Springer &  
23 Gatesy, 2015) as we perform here with ML and MP. Others, however, argued that  
24 incongruence was expected with a history of incomplete lineage sorting (e.g.,  
25 Linz, Radtke & Haeseler, 2007) and that the data should be analyzed by  
26 multispecies coalescent procedures that took this into account (e.g., Edwards  
27 et al., 2016). Which procedure is more appropriate, or whether different  
28 procedures are appropriate for different groups is still a matter of debate  
29 and we performed both here.  
30  
31

32 Figure 2 shows the SVD quartets multispecies coalescent results of  
33 allele set B run without *D. montanus*. Supplementary file 7 shows the allele  
34 set A and B trees with and without *D. montanus* and allele set B with *D.*  
35 *montanus*. Figure 2 shows many points of concordance and discordance with the  
36 ML and MP analysis (these two treated here as a single largely concordant  
37 result). While SVD maintains the same major clades (A, A', B) there many  
38 areas of disagreement of species within these two clades. For example, ML and  
39 MP resolve *Daucus montanus* as an allopolyploid between *D. pusillus* and *D.*

## DISCUSSION

The genus *Daucus* has been the focus of numerous phylogenetic studies. Most of these have been based on one or few DNA regions, mainly nuclear internal transcribed spacer regions (nrITS) (Spalik & Downie, 2007; Spalik et al., 2010; Lee & Park, 2014; Banasiak et al., 2016) which produced trees greatly helping to redefine relationships in *Daucus* and outgroups but sometimes with moderate to weak support in some terminals. Recently, phylogenetic trees constructed with single-to low-copy nuclear orthologous gene sequences (Arbizu et al., 2014a) have yielded phylogenies with stronger support and more consistent with morphological relationships among clades. In prior studies, incorrect identifications existed for members of the *D. guttatus* complex (including *D. bicolor* Sm., *D. broteri* Ten., *D. guttatus*, and *D. setulosus* Guss. ex DC.) which hindered the interpretation of trees based on morphology. Those misidentifications were corrected in Arbizu et al. (2016) and Martínez-Flores et al. (2016) and we here use this corrected nomenclature.

Previous studies found that members of *Daucus* (s.l.) are arranged into two well supported (96–100% bootstrap) clades (hereafter referred to as

1  
2  
3 clades A and B, with the species with  $2n = 18$  resolving into a subclade A').  
4  
5 Species in clade A were sister to the 'Macaronesian endemics group', section  
6  
7 *Melanoselinum* (Spalik & Downie, 2007; Banasiak *et al.*, 2016) including taxa  
8  
9 usually ascribed to the genera *Cryptotaenia* DC., *Melanoselinum* and *Monizia*.  
10  
11 These three genera are native to the Macaronesian region and have been  
12  
13 classified in other genera due to striking morphological traits deviating  
14  
15 from traditionally circumscribed *Daucus* species (detailed below). Species in  
16  
17 clade B are sister to members of *Agrocharis*, a genus native to central  
18  
19 tropical Africa. According to Lee (2002), *Agrocharis* characters of fruit  
20  
21 morphology (i.e., primary ridges with numerous papillate hairs, well-  
22  
23 developed secondary ridges, and single-rowed stout spines with glochidiate  
24  
25 apex) support a close relationship to *Daucus*, though with some striking  
26  
27 differences (i.e., petals yellow, yellowish-greenish or dark vs. white or  
28  
29 pinkish; and most spines of each ridge straight and retrorse) that allow easy  
30  
31 recognition separate from *Daucus* (Martínez-Flores, 2016). *Agrocharis* species  
32  
33 are tetraploids with  $2n = 44$ , a chromosome number infrequent within *Daucus*  
34  
35 and related taxa, which is shared only by *D. glochidiatus* (Constance &  
36 Chuang, 1982; Constance, Chuang & Bell, 1976; Iovene *et al.*, 2008).

37 Banasiak *et al.* (2016) obtained the most complete phylogenetic trees to  
38 date on this expanded *Daucus* (s.l.) clade, with nuclear (nrITS) and three  
39 plastid markers. Comparative studies of concordance and discordance in  
40 phylogenies built from various molecular markers (e.g., Wendel & Doyle, 1998)  
41 have shown that plastid phylogenies are the most discordant relative to other  
42 molecular markers, caused by various reasons. Spooner *et al.* (2017)  
43 demonstrated that these nuclear and plastid markers sometimes produce  
44 incongruent results. Our present results show additional significant  
45 incongruences that we interpret with morphological, chromosome and  
46 biogeographic data as discussed below.

12

3 CLADE B, *DAUCUS SETULOSUS* AND *DAUCUS ARCANUS*

5 Within clade B, most major subclades showed weak bootstrap support values in  
6 the combined nrDNA and plastid DNA tree of Banasiak et al. (2016). In our ML  
7 and MP phylogenetic trees, clade B is arranged into three subclades with  
8 strong support ( $BS \geq 90\%$ ), but as mentioned above, SVD trees often have  
9 different cladistic relationships within these clades, and with lower  
10 bootstrap supports. According to Banasiak et al. (2016), *D. setulosus* (from  
11 Greece) is sister to the '*guttatus-littoralis*' clade (from Israel and Egypt),  
12 but that relationship is weakly supported ( $BS = 46\%$ ). Conversely, our ML and  
13 MP results show *D. setulosus* as sister to the '*arcanus-pusillus*' clade (from  
14 the Americas and the Iberian Peninsula) with a strong support ( $BS \geq 90\%$ ).  
15 Although results by Banasiak et al. (2016) show low resolution for *D.*  
16 *setulosus*, some similarities are found with our tree, since their nrDNA ITS  
17 and combined plastid trees show the '*arcanus-pusillus*' clade sister to a  
18 clade including the '*setulosus*' plus the '*guttatus-littoralis*' group ( $BS =$   
19 49%), and *D. setulosus* is again nested with the '*arcanus-pusillus*' clade ( $BS =$   
20 31%) in their nrDNA ITS tree. Our SVD results, in contrast, resolve *D.*  
21 *setulosus* with *D. conchitae* and *D. littoralis*, but with low (52%) bootstrap  
22 support.  
23

24 Separately, all three of our results highlight a close relationship  
25 between the Iberian *D. arcanus* and *D. pusillus*, previously noted by Lee &  
26 Park (2014) based in nrITS data. After studying the morphology of both taxa,  
27 and despite of the often smaller size of *D. arcanus* (Fig. 3), we assume that  
28 the Iberian species fits well within the wide morphological plasticity  
29 observed for *D. pusillus* throughout South and North America. Thus, both taxa  
30 are treated here as conspecific, with *D. pusillus* the priority name. *Daucus*  
31 *arcanus* is only known from a few distant localities in southern Spain and  
32 Portugal (García-Martín & Silvestre, 1990; Martín-Blasco & Carrasco, 1997;  
33 Martínez-Flores, 2016; Porto & Pereira, 2018; E. Sánchez-Gullón, pers. comm.)  
34

(Fig. 4). The eventual connection between the New World to the Iberian Peninsula remains unclear. The mericarps of *D. pusillus* (incl. *D. arcanus*) are the smallest within the genus *Daucus* (Martínez-Flores, 2016) (Fig. 3B), and the fruits of genus *Daucus* are easily dispersed by wind and animals (Lacey, 1981; Okeke, 2015). Thus, the introduction of *D. arcanus* to the Iberian Peninsula could be the result of a long-distance dispersal similar to recent introductions of *D. glochidiatus* to Europe (Okeke, 2015), such as the wide dispersal of *D. carota* to South Africa and Australia (Burtt, 1991; Groves, 2003); a dispersal mechanism common in Apiaceae (Banasiak et al., 2013). The type locality of *D. arcanus* (Matalascañas, Doñana National Park) is about 40 km southwest from the ancient harbour of Palos de Moguer, in Huelva province, and about 30 km northwest from Sanlúcar de Barrameda (the entry to the harbour of Seville throughout the Guadalquivir river), in Seville province (Spain). After 1492, all this area received a large amount of maritime traffic from America, a fact that could explain the introduction of *D. pusillus* to southern Spain and Portugal.

CLADE B, *DAUCUS CONCHITAE* GREUTER AND *D. INVOLUCRATUS* SM.

The relationship between *D. conchitae* and *D. involucratus* is strongly supported in all our analyses (BS  $\geq 90\%$ ) and that of Banasiak et al. (2016). Banasiak et al. (2016) found that the 'conchitae-involucratus' clade was closely related to *D. bicolor* (BS = 99%). These three species grow in Turkey. Our ML and MP results resolve the 'conchitae-involucratus' clade as sister to all other species in clade B, whereas *D. bicolor* is included in a strongly supported (BS  $\geq 90\%$ ) wider clade also including *D. guttatus*, *D. littoralis* Sm., *D. durieua* and *D. glochidiatus*. Species within this wider clade inhabit mainly the eastern Mediterranean region (with *D. durieua* also present in the Iberian Peninsula and *D. glochidiatus* being endemic to Oceania). SVD, in contrast, resolve *D. conchitae* and *D. involucratus* as very weakly supported

(52% bootstrap) sister to *D. setulosus* (these three species growing along the lands surrounding the Aegean Sea).

CLADE B, *DAUCUS DURIEUA* AND THE ALLOPOLYPLOID *D. MONTANUS*

In Banasiak et al. (2016) and in all three analyses of our present study, as in other recent phylogenies, the position of *D. durieua* remains unclear. According to Banasiak et al. (2016), it is sister to the '*glochidiatus-montanus*' clade in a weakly supported relationship (BS = 64%). Our results (Fig. 1) are similar, but our ML and MP evidence supports an allopolyploid origin of *D. montanus* from *D. glochidiatus* and *D. pusillus*. *Daucus montanus* and *D. glochidiatus* are morphologically similar (i.e., pollen shape and ornamentation, leaf indumentum, bract number, petal shape and size, mericarp length, style length, relative size of glochidia). *Daucus montanus* and *D. pusillus* also share several morphological characteristics such as petal shape and size, style length, anther size and pollen features (Sáenz, 1981; Okeke, 2015; Martínez-Flores, 2016). *Daucus glochidiatus* is found in Oceania and its chromosome number is  $2n = 44$ , whereas *D. pusillus* inhabits North and South America and its chromosome number is  $2n = 22$ . Finally, *D. montanus* occurs in Central and South America and its chromosome number is  $2n = 66$ . The three species therefore share the basic number  $x = 11$  (Constance et al., 1976; Iovene et al., 2008; Okeke, 2015). Spalik et al. (2010) suggested several *Daucus* dispersal events from the Old World to the New World and, successively, a dispersal from South America to Australia (during the late Pliocene). Our ML and MP results highlight a relationship between the Australian *D. glochidiatus* and the American *D. pusillus*. Nevertheless, there are no records of *D. glochidiatus* today in South America where *D. pusillus* and *D. montanus* grow, so the likely mechanism of the hybrid origin of *D. montanus* involving these species is unclear and would remain entirely

1  
2  
3 speculative. This hypothesis is better supported by our results than an  
4 eventual autoployploidy from *D. pusillus* as Okeke (2015) suggested.  
5  
6  
7  
8  
9 CLADE A – THE MACARONESIAN TAXA  
10  
11 Clade A groups several *Daucus* species, encompassing the type of the genus, *D.*  
12 *carota*. As well, taxa traditionally included in other genera, such as  
13 *Cryptotaenia*, *Melanoselinum*, *Monizia*, *Pseudorlaya* and *Tornabenea* also occur  
14 in clade A. According to the phylogenetic tree of Banasiak et al. (2016), the  
15 'Melanoselinum-Monizia' clade is sister to the remaining species in clade A.  
16  
17 The rest of that clade forms a group with a weak support (BS = 67%),  
18 including *Cryptotaenia elegans* in a basal position. These relationships  
19 remain unresolved in their plastid DNA trees.  
20  
21 Relative to Banasiak et al. (2016), our ML and MP results show a  
22 strongly supported 'crinitus-setifolius-tenuisectus' clade sister to the  
23 'Melanoselinum-Monizia' clade and the remaining groups of clade A  
24 (*Cryptotaenia* was not analysed). The SVD results are quite different with *D.*  
25 *tenuisectus* as sister to all remaining species in clade A, and quite  
26 different interspecific relationships among the remaining species, but the  
27 Macaronesian species maintained in its own well-supported clades. These  
28 Macaronesian taxa show characters very different from the classic concept of  
29 genus *Daucus*. All three produce mericarps without spines. *Cryptotaenia*  
30  
31 *elegans* is distinguished by a reduced or absent involucre and mericarps  
32 lacking secondary ridges and trichomes on the primary ridges (Martínez-  
33 Flores, 2016). Its chromosome number  $2n = 16$  (Suda, Kyncl & Jarolímová, 2005)  
34 is only shared by both species in *Pseudorlaya*. *Melanoselinum decipiens* and  
35 *Monizia edulis* differ from the rest of species in several characteristics as  
36 long-life span, small tree-sized habit, very long (7.6–16.8 mm) dorsally  
37 compressed mericarps with dorsal secondary ridges clearly smaller than the  
38 lateral ones and hypertrophied commissural vitae (Martínez-Flores, 2016).

1  
2  
3  
4  
5 CLADE A, *DAUCUS MURICATUS* L. AND *D. TENUISECTUS* Coss. EX BATT.  
67 In Banasiak *et al.* (2016), a 'muricatus-tenuisectus' clade (BS = 70% in their  
8 study) is sister to the remaining *Daucus* species in clade A, except for the  
9 'Macaronesian group' being successive sister groups of the whole aggregate).  
10 Conversely, our ML and MP results place *D. tenuisectus* in a strongly  
11 supported clade (92% BS) containing *D. crinitus* and *D. setifolius* (*sensu*  
12 *lato*) whereas *D. muricatus* and *D. aureus* are sister in a separate moderately  
13 supported clade (Fig. 1). And our SVD analysis resolves *D. tenuisectus* as  
14 sister to the other species in clade A (Fig. 2).  
15  
1617  
18  
19  
20  
21  
22  
23  
24 *Daucus aureus* and *D. muricatus* have many morphological features suggesting  
25 they are sister, such as the extreme reduction of vitae, the ray indumentum,  
26 the reflexed bracts (Martínez-Flores, Juan & Crespo, 2012), the pollen  
27 ornamentation and the primary commissural ridges crowded together (Martínez-  
28 Flores, 2016). The position of *D. tenuisectus*, though strongly supported in  
29 our ML and MP analysis, is ambiguous in previous studies. The nrITS  
30 phylogenetic tree in Banasiak *et al.* (2016) placed *D. tenuisectus* together  
31 with *D. muricatus* in a weakly supported clade (BS = 60%). However, their  
32 plastid DNA data indicated that *D. tenuisectus* could be closer to *Rouya*  
33 *polygama* Coincy, *D. syrticus* and *D. carota*, although resolution is weak (BS =  
34 54%). The most evident morphological features seem insufficient to clarify *D.*  
35 *tenuisectus* affinities, and further detailed studies are therefore needed.

47  
48  
4950 CLADE A -*DAUCUS CRINITUS* AND *DAUCUS SETIFOLIUS*  
51  
52 Both Banasiak *et al.* (2016) and our phylogenetic analysis demonstrate that *D.*  
53 *crinitus* and *D. setifolius* are strongly supported sister taxa (BS ≥ 90%).  
54 These species show distinctive morphological characters from other *Daucus*.  
55 They are the only species to be polycarpic hemicryptophytes, producing leaves  
56  
57  
58  
59  
60

1  
2  
3 with filiform to very narrow segments apparently verticillate  
4 (pseudoverticillate), and producing mericarps elongate (up to 7.2-8.0 mm  
5 long; mean ratio length/width ± 4.3-4.9), with soft spines, glochidia reduced  
6 to a short straight apex and styles very long (up to 3.5-3.9 mm) (Martínez-  
7 Flores, 2016). Both species are found in the western Mediterranean (Tunisia,  
8 Algeria, Morocco, Spain and Portugal, Fig. 5), and they share the diploid  
9 chromosome number  $2n = 22$  (Aparicio & Silvestre, 1985; Silvestre, 1993 [as  
10 "*D. brachylobus* Boiss."]). We here distinguish two distinct species formerly  
11 referred to as *D. setifolius* (Fig. 6). Both have very similar mericarps but  
12 they can be easily differentiated by the indumentum of stems and leaf  
13 sheaths, the branching pattern and their allopatric distribution. The typical  
14 *D. setifolius* shows an indumentum of minute retrorse trichomes on the basal  
15 third of stem and leaf sheaths; it produces numerous long primary and  
16 secondary branches in a common Apiaceae branching pattern with long  
17 pedunculate umbels (Fig. 6A,B), and grows in northern Morocco, Algeria and  
18 Tunisia, along the Atlas mountains, with only a single Spanish population in  
19 the western Penibetic mountains (Málaga province) (Fig. 5, squares). On the  
20 contrary, *D. junceus* exhibits an indumentum of antrorse trichomes on the  
21 basal third of stem and leaf sheaths (an exclusive character not found in any  
22 other representative of clade A), and it has very short pedunculated to  
23 sessile umbels, with very few or no primary branches, forming a  
24 distinctive branching pattern within *Daucus* (Fig. 6C,D), resembling a *Juncus*  
25 L. species. That rush-like morphology led Willkomm (1851) to describe it as  
26 *Durieua juncea*. According to our research, *D. junceus* is endemic to  
27 southwestern Iberian Peninsula along the river basins and surrounding  
28 mountains (Fig. 5, circles and asterisks). Our phylogenetic results are  
29 congruent with the recognition of two morphologically distinct species. The  
30 Banasiak et al. (2016) plastid DNA tree also analysed *D. junceus* (Spanish *D.*  
31 *setifolius* 237 collected in Seville province) and is likewise separated from  
32

2       *D. setifolius* (Algerian 467 and Spanish G56 collected in Málaga province).

3  
4 Both species are not clearly separated in their combined analysis, possibly  
5 due to plastid/ITS incongruence, or different plastid/ITS analysed taxa.

6  
7  
8  
9  
10                          CLADE A, DAUCUS MAIN GROUP PLUS CLADE A'

11  
12 Regarding the remaining groups within clade A, our phylogenetic analysis  
13 coincides with results in Banasiak et al. (2016). The '*Pseudorlaya* clade' (*D.*  
14 *minusculus* and *D. pumilus*) is highly supported (BS  $\geq 90\%$ ), and sister to the  
15 remaining clades. Both of these species have a distinctive morphological  
16 syndrome: annual habit, zygomorphic umbels (both involucre and rays  
17 arrangement), short styles (0.4–0.9 mm), mericarps with two rows of spines  
18 per ridge and sparse indumentum in primary commissural ridges (0–5  
19 trichomes/mm) (Martínez-Flores, 2016), and both share the same chromosome  
20 number  $2n = 16$  (García-Martin & Silvestre, 1985; Vogt & Oberprieler, 1994;  
21 Mohamed, 1997). *Daucus rouyi* is placed between the '*Pseudorlaya* clade' and  
22 the '*Daucus* main group' plus clade A'. *Daucus rouyi* formerly was the sole  
23 member of a monotypic genus, *Rouya*, found in a reduced area in northern  
24 Corsica, Sardinia, northeastern Algeria and northern Tunisia. It is well  
25 characterised by its polycarpic chamaephytic habit, the small erect petals ( $\pm$   
26 1.3 mm), the widely winged mericarps (1.9–3.1 mm width), lack of spines on  
27 secondary ridges and lack of trichomes on primary ridges, (Martínez-Flores,  
28 2016), and a chromosome number  $2n = 20$  (Constance et al., 1976). The  
29 remaining *Daucus* species (clade A') share a chromosome number  $2n = 18$  (Reese,  
30 1957; Grosso et al., 2008; Iovene et al., 2008), patent petals usually longer  
31 than 1.3 mm, mostly spiny and not clearly winged secondary ridges, primary  
32 ridges with indumentum, and according to our molecular phylogenetic studies  
33 are nested in a strongly supported clade (BS  $\geq 90\%$ ). *Daucus gracilis* (unknown  
34 chromosome number) is sister to these species while *D. syrticus* Murb. is  
35 sister to the 'carota-Tornabenea' (*D. annuus* and *D. tenuissimus*) clade. The  
36  
37

55  
56  
57  
58  
59  
60

1  
2  
3 former genus *Tornabenea* includes several species endemic of Cape Verde, which  
4 are characterised mainly by fruits with very narrowly 'winged' secondary  
5 ridges. However, Martinez-Flores (2016) found that morphological characters  
6 in the former genus *Tornabenea* such as the mericarp size, vitae shape, style  
7 length, or pollen size and ornamentation, are very similar to those in *D.*  
8 *carota*, and even extremely reduced spines can be observed on the mericarp  
9 narrow 'wings', like in some taxa in the complex of *D. carota* (Pujadas-Salvà,  
10 2003). Different chromosome numbers were reported within these species.  
11  
12 Brochman et al. (1997) and Grosso et al. (2008) indicated  $2n = 18$  for *Daucus*  
13 *annuus* and *D. insularis* (=*T. insularis* (Parl.) Parl.), and Bramwell & Murray  
14 (1972)  $2n = 18$  for *T. hirta* J.A.Schmidt (no *Daucus* name to date). However,  
15 Borgen (1980) reported  $2n = 16$  for *T. hirta* and Borgen (1974) indicated the  
16 same latter number for *D. tenuissimus*, while Bramwell & Murray (1972) found  
17  $2n = 22$  in *T. bischoffii* J.A.Schmidt (no *Daucus* name to date). According to  
18 our results,  $2n = 18$  is congruent with the former members of *Tornabenea*  
19 closely related to *Daucus carota*, and based on those facts, some of those  
20 species may be included in the genus *Daucus*, as formally transferred by  
21 Banasiak et al. (2016). In summary, notable discrepancies exist on the  
22 taxonomy of these former members of *Tornabenea*, both in morphology (Grosso et  
23 al., 2008) and in chromosome numbers (Bramwell & Murray, 1972; Borgen, 1974,  
24 1980; Brochman et al., 1997; Grosso et al., 2008). No molecular and  
25 morphological revision of these species is available and they are in need of  
26 further detailed analyses.

*Daucus brachylobus* Boiss., Voy. Bot. Espagne 2: 258, t. 68. 1840.

**Lectotype (designated here):** [ALGERIA]. Prope Mascar in collibus incultis, Desfontaines (P-00320312!). Isolectotypes: G-00023270 (digital image!), MPU-021024 (digital image!). Note: Previous indication of "holotype" in the electronic publication of Okeke's (2015) PhD thesis should be regarded as "lectotype", but such typification is not effective according to Art. 29.1 of the ICN (Turland *et al.*, 2018) since that publication lacks ISBN, ISSN or doi number. The lectotype designated here is a specimen from Desfontaines's "*Herbier de la Flore Atlantique*" among the historical collections at P.

Ind. loc.: 'Habitat prope Mascar in collibus incultis' [Algeria]

Brief description: Polycarpic hemicryptophyte; stems minutely pubescent at the basal third, with retrorse trichomes; primary and secondary stem branches numerous and elongated, with long pedunculated umbels; leaves with basal sheath covered with retrorse trichomes, and with filiform to very narrow segments apparently verticillate (pseudoverticillate); mericarps elongate cylindric-ovoid, mostly covered with a dense indumentum, secondary ridges with soft spines and glochidia reduced to a short straight apex, styles very long, vittae subtriangular in section.

Chromosome number:  $2n = 22$  ( $n = 11$ ; Silvestre, 1993 [as *D. brachylobus* Boiss.]).

Ecology: Degraded brushwood areas, often in rocky places. Usually on ultrabasic substrates (i.e., peridotites, serpentines) and sometimes on acid ones (i.e., basalts, sandstones).

Distribution: Morocco, northern Algeria and northern Tunisia along the Atlas Mountains, with only a relict Spanish population in the western Penibetic Mountains (Málaga province).

Selected specimens: see Appendix.

***Daucus junceus* (Willk.) Mart.Flores & M.B.Crespo, comb. nov.**

*Durieua juncea* Willk. in Flora 34: 711. 1851 [basion.]

**Lectotype (designated here):** [SPAIN]. "76. d. (coll. sel.) / *Durieua hispanica* ?-Beiss. Reut. [cross outs literal transcription of the label] / *juncea*, Willk! / in graminosis inter frutices / in solo granitico declivium vallis / fluvii Jerte pr. Plasencia in / Extremadura, 10/1850 / legit Willk.) (BM-000752080 [digital image!]. Isolectotype: P-02461299 [digital image!]).

Ind. loc.: 'Hab. in graminosis inter saxa granitica in valle fluvii Jerte prope Plasencia in Extremadura hinc inde' [Spain]. Pl. ex. coll. ven. select. n. 76 d.

Diagnosis: Very akin to *D. setifolius* from which it differs mainly by the stems covered at the basal third with antrorse trichomes, identical to those coating the leaf sheaths (an exclusive character not found in any other representative of clade A); and by the primary branches absent or very scarce, bearing subsessile to very shortly pedunculated umbels (often several small umbels grouped together).

22

1  
2 Chromosome number:  $2n = 22$  ( $n = 11$ ; Aparicio & Silvestre, 1985 [as "*D.*  
3 *setifolius*"]).

4  
5 Ecology: Roadsides, borders of fields and degraded brushwood areas, often  
6 near rivers. Usually on acid substrates (i.e., granites, schists, etc.).

7  
8 Distribution: Endemic to southwestern Iberian Peninsula along the river  
9 basins (Guadalquivir, Guadiana, Tajo) and surrounding mountains. Only one  
10 population had been reported to the north of that indicated area (Almeida et  
11 al., 2009). Unfortunately, that population was destroyed due to the  
12 construction of a dam (C. Aguiar, pers. comm.).

13  
14 Selected specimens: see Appendix.

5     **Lectotype (designated here):** [USA]. "Daucus pusillus / in sabulosis /  
6     Carolinae" (P-00320342!). Note: Previous indication of "holotype" in the  
7     electronic publication of Okeke's (2015) PhD thesis should be regarded as  
8     "lectotype", but such typification is not effective according to Art. 29.1  
9     of the ICN (Turland *et al.*, 2018) since that publication lacks ISBN, ISSN  
10     or doi number. Furthermore, the Canadian voucher selected by that author,  
11     "In America bor. occid. ad Nootka-Soud", Haenke (G-DC)", is not acceptable  
12     since it cannot be regarded as original material of *D. pusillus* (Michaux,  
13     1803). The lectotype designated here is a specimen from "Herbier de  
14     l'Amérique septentrionale d'André Michaux" at P, collected in Carolina and  
15     matching with the protologue of that name.

#### ACKNOWLEDGEMENTS

We thank the curators and staff of the herbaria ABH, BM, COA, COI, FCO, MA, LISI, P and SEV for help with the studied material. We also thank A. Aparicio, G. Blanca, M. Cueto, J. Fuentes, F. García-Martin, J. Pastor, Rodríguez-Cobo and A. Sánchez for kindly providing some specimens of *Daucus junceus*, *D. pusillus* (*ut D. arcanus*) and *D. setifolius*. Cécile Aupic (MNHN, Paris) provided with images of the original material of Michaux's *Daucus pusillus*, and helped with consultation of Desfontaines's herbarium at P. Jean-Pierre Reduron (Via Apia, France) helped with the material provided by Agrocampus Ouest IRHS. Pieter de Winter (SANBI, South Africa) forwarded data on the introduction of *D. carota* in southern Africa. This research was partly funded by the research grant UA2004-47056131 (University of Alicante) to FMF.

## FIGURE LEGENDS

**Figure 1.** Strict consensus maximum parsimony tree of 48, 8341-length trees constructed with 10 nuclear orthologous gene sequences of allele set B, without *Daucus montanus*, but with this species drawn in manually based on individual allele results supporting it as an allopolyploid species between *D. pusillus* and *D. glochidiatus*. Chromosome numbers supporting these clades (Table 2) are shown in blue bracketed type and bootstrap support values in black non-bracketed type.

**Figure 2.** Singular-value decomposition (SVD) quartets analysis using the multispecies coalescent option with 100 bootstrap replicates constructed with 10 nuclear orthologous gene sequences of allele set B, without *Daucus montanus*. With *D. montanus* this species is supported as an allopolyploid between *D. pusillus* and an unidentified species. Chromosome numbers supporting these clades (Table 2) are shown in blue bracketed type and bootstrap support values in black non-bracketed type.

**Figure 3.** Specimen of *Daucus pusillus* Michx. (including *D. arcanus* García Martín & Silvestre) collected in Ciudad Real, Spain (ABH78367): A, habit; B, detail of fruiting umbels.

**Figure 4.** Distribution of *Daucus pusillus* Michx. (including *D. arcanus* García Martín & Silvestre) in the Iberian Peninsula. See Appendix for a detailed list of records.

**Figure 5.** Distribution of *Daucus junceus* (Willk.) Mart. Flores & M.B.Crespo (circles) and *D. setifolius* Desf. (squares), based on studied herbarium specimens and reliable photographic records. Asterisks indicate trustworthy

<sup>a</sup>DNA sequences and locality data of the 85 accessions not listed here were obtained from Arbizu et al. (2014, 2016).

<sup>b</sup>Ames numbers are assigned for carrots and other Apiaceae in the US National Plant Germplasm System temporarily to newly acquired germplasm until passport data of an accession and taxonomy is verified. In addition, accessions with Ames numbers have to be determined they are not duplicate accession, and that they can be successfully maintained. These accessions may or may not be assigned a PI number after the assessment period.

**Table 2.** Chromosome numbers of the species examined here. We found no references for chromosome numbers for *Daucus bicolor*, *D. conchitae* and *D. gracilis*.

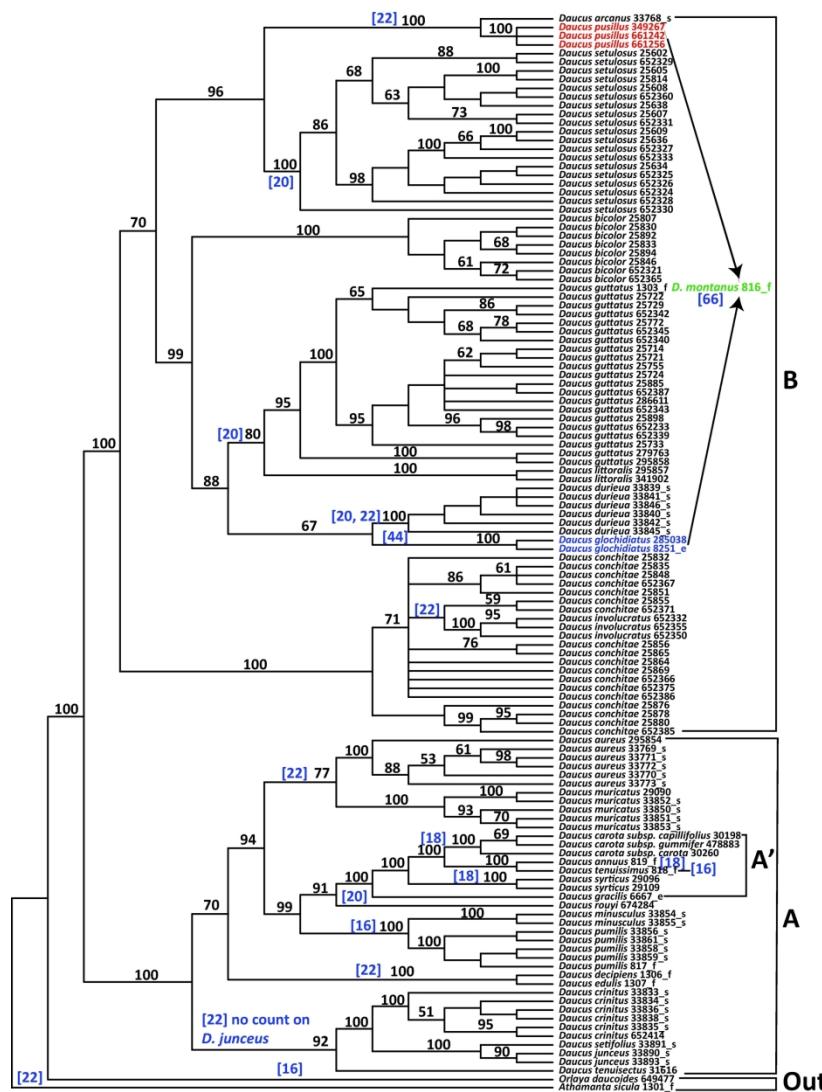

Figure 1. Strict consensus maximum parsimony tree of 48, 8341-length trees constructed with 10 nuclear orthologous gene sequences of allele set B, without *Daucus montanus*, but with this species drawn in manually based on individual allele results supporting it as an allopolyploid species between *D. pusillus* and *D. glochidiatus*. Chromosome numbers supporting these clades (Table 2) are shown in blue bracketed type and bootstrap support values in black non-bracketed type.

223x256mm (300 x 300 DPI)

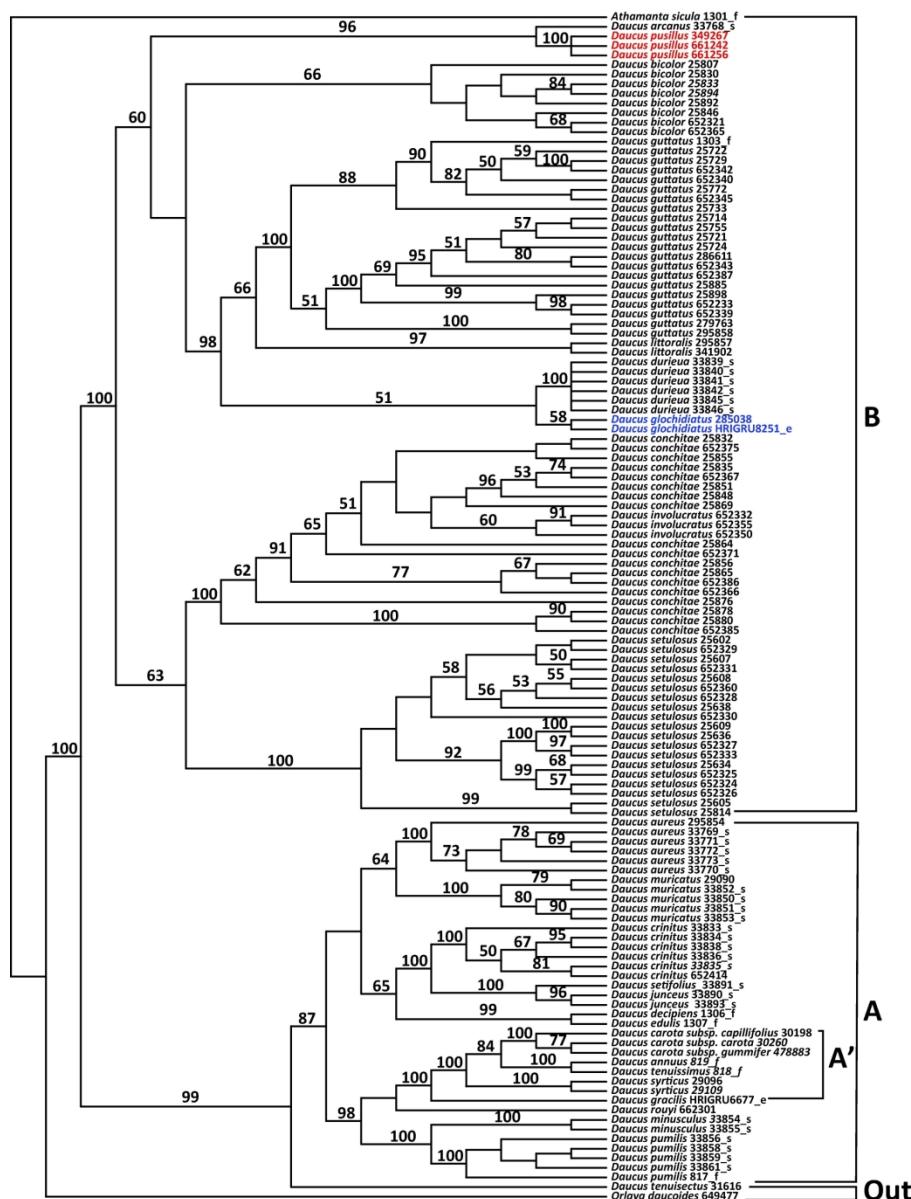

Figure 2. Singular-value decomposition (SVD) quartets analysis using the multispecies coalescent option with 100 bootstrap replicates constructed with 10 nuclear orthologous gene sequences of allele set B, without *Daucus montanus*. With *D. montanus* this species is supported as an allopolyploid between *D. pusillus* and an unidentified species. Chromosome numbers supporting these clades (Table 2) are shown in blue bracketed type and bootstrap support values in black non-bracketed type.

187x243mm (300 x 300 DPI)

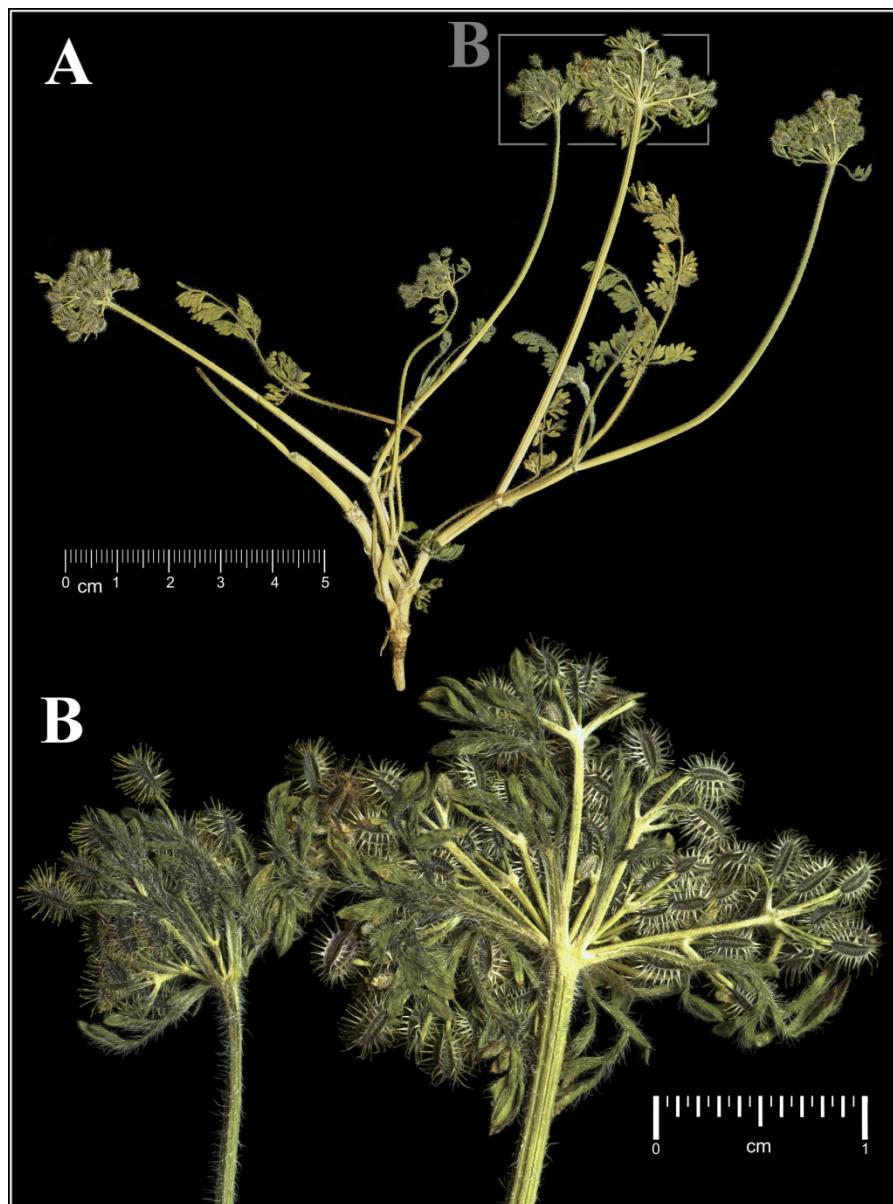

Figure 3. Specimen of *Daucus pusillus* Michx. (including *D. arcanus* García Martín & Silvestre) collected in Ciudad Real, Spain (ABH78367): A, habit; B, detail of fruiting umbels.

167x224mm (300 x 300 DPI)

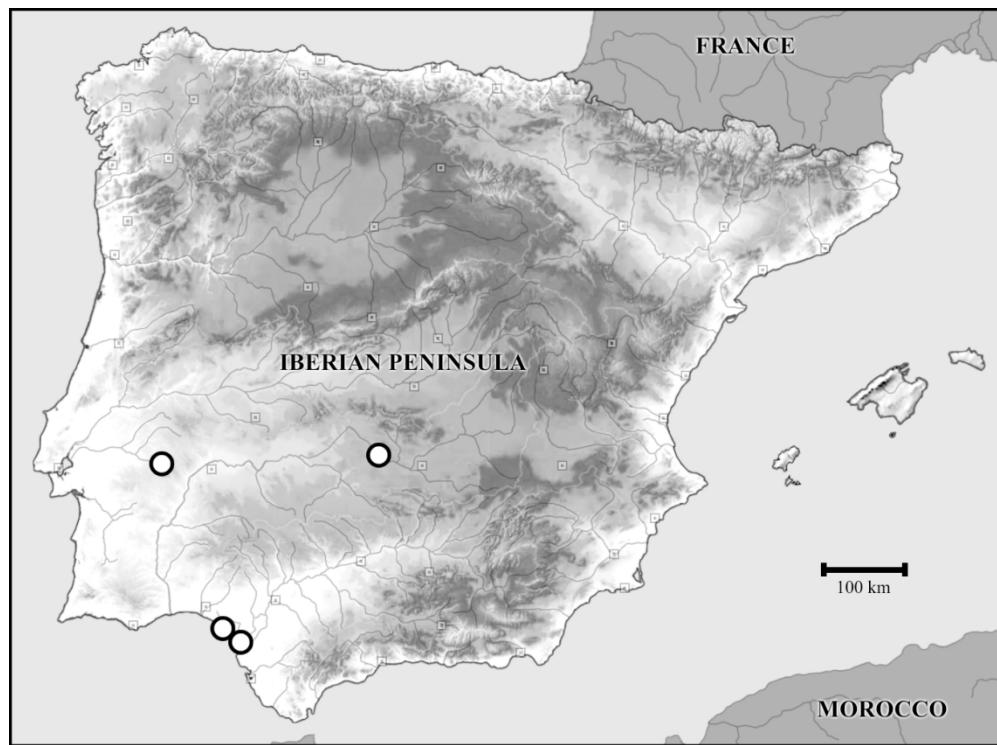

Figure 4. Distribution of *Daucus pusillus* Michx. (including *D. arcanus* García Martín & Silvestre) in the Iberian Peninsula. See Appendix for a detailed list of records.

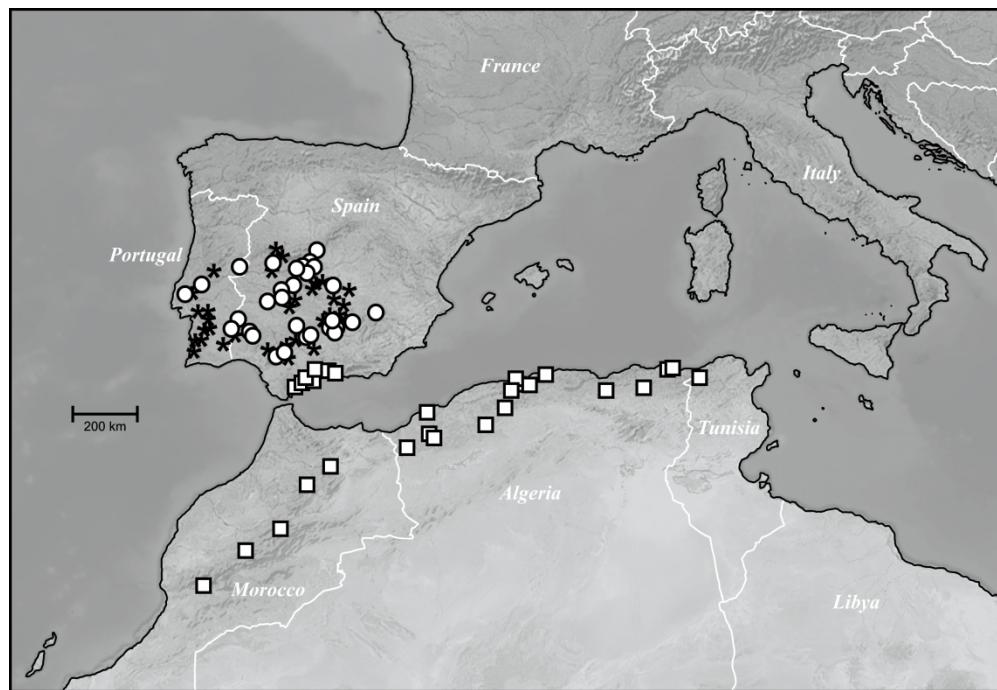

Figure 5. Distribution of *Daucus junceus* (Willk.) Mart.Flores & M.B.Crespo (circles) and *D. setifolius* Desf. (squares), based on studied herbarium specimens and reliable photographic records. Asterisks indicate trustworthy bibliographic references and databases for *D. junceus*. See Appendix for a detailed list of records.

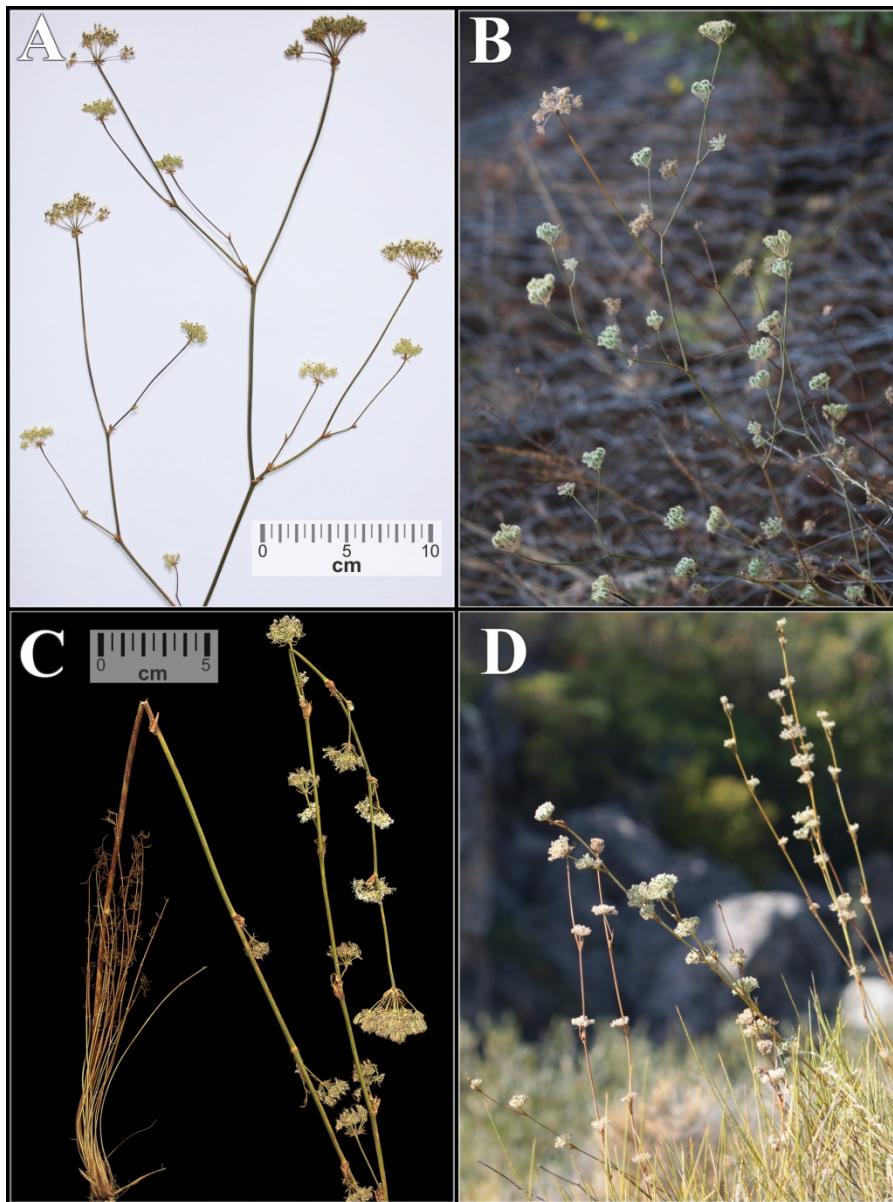

Figure 6. Specimens of *Daucus junceus* (Willk.) Mart.Flores & M.B.Crespo and *D. setifolius* Desf. *Daucus setifolius* A: herbarium specimen ABH78370 collected in Málaga, Spain; B: natural population of *D. setifolius* from Málaga, Spain, accession E-107; *D. junceus* C: herbarium specimen ABH53906 collected in Seville, Spain; D: natural population of *D. junceus* from Jaén, Spain, accession Ames 33893.
