Abstract

As calls for more socially responsible research and innovation (RRI) policies and practices grow more insistent, the need for high quality indicators that can be used to evaluate progress is becoming increasingly important. Given the global nature of science, such indicators need to be relevant to countries across all world regions. Moreover, the methodological quality of indicators is critical to provide a strong foundation for long-term comparative measurement of the impacts of different kinds of policy intervention. There is a practical challenge in this effort relating to the uneven mechanisms for data collection and analysis available in different countries. There is also a geopolitical challenge in gaining buy-in from countries with very different, and sometimes competing, agendas. Here, the 2017 UNESCO-led Recommendation on Science and Scientific Researchers is highlighted as an existing vehicle that can enable cooperation on globally comparative measurement of socially responsible research and innovation. In particular, the quadrennial monitoring of the implementation of this wide-ranging global policy instrument that has been ratified by 195 countries affords a unique opportunity to add value for these countries by linking RRI to the 2017 Recommendation while establishing benchmark indicators for RRI more generally. As a practical and methodological contribution to the global community of science and innovation policymakers, researchers and research and innovation stakeholders committed to socially responsible research, this report contains detailed survey questions and response options focusing on public opinion and individual researchers' level of measurement. It provides details of sources of benchmark survey data that have readily available open data that can be used to benchmark the development of socially responsible research and

Plain language summary

The United Nations is overseeing a global effort to improve scientific research policy and practices. This effort requires good metrics to measure progress. Developing appropriate metrics for good policy and practice in science systems is complicated, especially when trying to align approaches globally. This paper offers ideas about how this measurement task can be achieved at the level of public opinion and individual researchers. The recommended approach saves resources and improves quality by using existing metrics and data.

Introduction

Responsible research and innovation (RRI) has been a key priority for the European Union for many years. In recent years, the need for high quality measurement approaches to evaluate responsible research and innovation policies and practices has become increasingly apparent. Establishing globally relevant and usable indicators for RRI is challenging but essential, given the global nature of science. Ensuring these indicators are methodologically robust is important but must be balanced against practical constraints facing measurement initiatives in this domain (Jensen, 2020a; Jensen, 2020b; Jensen & Lister, 2015). Indeed, there is a practical challenge in this effort relating to the uneven mechanisms for data collection and analysis available in different countries (e.g., Heras *et al.*, 2016; Heras & Ruiz-Mallén, 2017).

The geopolitical challenge of gaining consensus and buy-in from countries with very different and sometimes competing agendas to align their RRI indicators can be addressed in part by tethering those indicators to a shared global policy instrument. In this essay, the 2017 UNESCO-led Recommendation on Science and Scientific Researchers (RSSR) (UNESCO, 2017) is highlighted as an existing vehicle that can enable cooperation on globally comparative measurement of socially responsible research and innovation. Numerous aspects of RRI that are enshrined in the RSSR have implications for public views on the role of science. Therefore, it is worth considering including an indicator dimension that focuses on the public aspect of the RSSR priority areas. The framework focuses on aligning the public opinion level of measurement to benchmark global survey measures, where feasible, such as the Wellcome Global Monitor (WGM) (wellcome.org/reports/wellcome-global-monitor-mental-health/2020) (wellcome.org/reports/wellcome-global-monitor-mental-health/2020).

In particular, the quadrennial monitoring of the implementation of this wide-ranging global policy instrument that has been ratified by 195 countries affords a unique opportunity to add value for these countries by linking RRI to the Recommendation while establishing benchmark indicators for RRI more generally. As a practical and methodological contribution to the global community of science and innovation policymakers, researchers, and research and innovation stakeholders committed to socially responsible research, this essay contains specific, detailed survey questions and response options focusing on the public opinion and individual researcher level of measurement.

It provides details of sources of international survey data that are readily available for secondary analysis to benchmark the development of socially responsible research and innovation over time from the vantage point of the public opinion.

10 key priority areas were identified and agreed by UNESCO Member States as a practical way to simplify and focus RSSR implementation and long-term monitoring, given the sprawling coverage of the full policy text (see Jensen, 2022a). This document outlines benchmark survey indicators and concomitant open data sources pegged to these 10 key priority areas that can be used to evaluate the development of RRI principles that are integral to the RSSR policy instrument. This measurement approach also allows for the fact that many of the principles included in the RSSR are already in evidence to some extent at different levels of national research systems, yet the extent to which this is recognised by public opinion is not well established.

Public opinion level of measurement for global RRI indicators

This manuscript goes beyond the current state of the art by presenting a framework of indicators that can be used to gain an understanding of RRI progress at the public level. This public level of measurement is often overlooked in a focus on national statistics and research and innovation *per se*, but the public's perspective on progress towards ever more socially sustainable science and innovation is essential to the long-term health of research and innovation ecosystems globally. Providing RRI indicators at this level of measurement offers specific ways to improve on existing RRI indicators and better support evidence-based practice in this domain (Jensen & Gerber, 2020).

The checklist icon (left) in this document highlights questions linked directly to the formal national reporting (UNESCO, 2021) for the UNESCO-led Recommendation on Science and Scientific Researchers RSSR (UNESCO, 2017). Answers to these overarching questions guide the reader to parts of the document likely to be most relevant. This is designed to highlight relevant RRI measures and indicators that have clear links to the long-term monitoring of the RSSR's implementation.

Direct quotations from the RSSR are included in grey font in the underlying data (Jensen, 2022b) to help clarify the different aspects of the categories included in the 10 key priority areas.

Here, indicators are documented that can provide evidence relevant to the public opinion level of responsible research and innovation indicators. Here, these indicators are organised according to the 10 key priority areas for the UNESCO RSSR. This section of the report describes the sources of global survey data that have been used to provide these indicators.

Wellcome Global Monitor (WGM). The only public attitudes to science and health survey conducted on a truly global scale is the Wellcome Global Monitor (wellcome.org/reports/wellcome-global-monitor-mental-health/2020). Crucially, this survey follows good industry standard practices for quality assurance, and it has collected data using probability-based sampling methods from people 15 years or older in over 140 countries. It also gathers demographic data on variables such as education, nationality, gender, and income. The mean number of respondents per country covered is 1,000. The survey was undertaken in 2018 and 2020-21.

Pew Research Center – International science survey questionnaire (Pew ISSQ). The international science survey of science and society topics includes the extent of public trust in scientists, consumption of science news, views about science policy, and government investment in science, as well as a range of other related topics (pewresearch.org/science/dataset/international-science-survey). Most recently, 20 countries were covered by this survey in 2019-2020 (age 18+ sample) with a wide geographical spread.

World Values Survey (WVS). The world values survey's most recent iteration was conducted between 2017 and 2020 (worldvaluessurvey.org/wvs.jsp). In this dataset, there are relevant survey questions to RRI and the country coverage is extensive, including 49 nations from a wide range of geographically dispersed regions.

Special Eurobarometer ‘public perceptions of science, research and innovation’. A special Eurobarometer survey was carried in 2014, focusing on European Union (EU) citizens' attitudes about scientific research and related issues (data.europa.eu/data/datasets/s2047_81_5_419_eng?locale=en). This survey covered countries across Europe.

3M State of Science Index Survey. The 3M annual state of science index measures science attitudes in 14 countries, focusing on various aspects of public views about science (3m.com/3M/en_US/state-of-science-index-survey/about-the-survey). With an average sample size of 1,000 for consistency, the survey has been gradually adding additional country coverage over time, and already spans different world regions.

SFI Science in Ireland Barometer survey. This survey was conducted in 2020-2021 in Ireland (<https://www.sfi.ie/engagement/barometer>). It followed robust methodological procedures in the set-up, piloting/validation, and implementation of the survey design, covering a wide range of RRI-related topics. Survey questions from this project are used where preceding surveys do not offer relevant metrics.

Individual researcher level of measurement for global RRI indicators

This essay goes well beyond the state of the art by presenting a framework of indicators that can be used to gain an understanding

of RRI progress at the individual researcher level. These indicators are mapped directly to the formal national reporting (UNESCO, 2021) for the UNESCO-led Recommendation on Science and Scientific Researchers (RSSR) (UNESCO, 2017).

This report documents indicators that can provide evidence relevant to the individual researchers' level of socially responsible research and innovation indicators (Jensen, 2022b). Here, these indicators are organised according to the 10 key priority areas for the UNESCO RSSR. This section of the report describes the sources of global survey data that have been used to provide these indicators, and that research and science policy stakeholders around the world can use to assess their current status with responsible research and innovation.

RRING survey on socially responsible research/innovation.

A global survey was launched as a part of the Responsible Research and Innovation Networked Globally (RRING) project (zenodo.org/communities/rring). The survey was open from 1st October 2019 to 20th December 2019. Aiming to get a deeper insight into the practices and policies of responsible research and innovation (RRI) across the world, this study was conducted across 20 countries. Diversity was ensured across factors such as the research and development expenditures, per capita income levels, etc., while selecting the countries to prioritise for saturation sampling (a mix of locally organised data collection in selected countries and an overall open call for responses, with email-based participation requests, was used).

The survey gathered 2,198 survey responses (70+% complete) and 539 surveys under 70% complete. Mean completion time for respondents was 33 minutes (dataset available: <https://doi.org/10.5281/zenodo.5031585>).

Organisation for Economic Co-operation and Development (OECD) International Survey of Scientific Authors.

As an online survey conducted worldwide, the international survey of scientific authors (ISSA) aims to evaluate science's development in its use of digital tools (oecd.org/science/survey-of-scientific-authors.htm). It gathered responses from close to 12,000 scientific authors. The survey was conducted under the auspices of the OECD-organized Working Party of National Experts of Science and Technology Indicators (NESTI) (<https://community.oecd.org/docs/DOC-174112>).

The study targeted the corresponding authors of scientific publications whose contact information is available in a large global bibliographic database. A sample of scientific authors listed as corresponding authors received participation requests directly from the OECD and were asked to report on their use of a broad range of digital tools and related practices, in addition to another key demographic and career information. Responses were collected for a total of approximately 12,000 scientific authors from all over the world and across all disciplinary areas, representing to a varying extent the subset of the research population engaged in scholarly publication work, including those in the business sector.

Frontiers' Academic response to COVID-19 survey. Frontiers is an open access research publisher and open science platform (apo.org.au/node/309304). Frontiers commissioned a survey focusing on how the COVID-19 pandemic has affected the practice of science around the world, using its database of active researchers who have published their research with Frontiers or have acted as reviewers or editors.

The survey was conducted in May-June 2020. A total of 25,307 respondents from 152 countries answered at least one question and 17,644 completed the entire fully anonymised survey. The 30 countries all had more than 100 respondents and make up 88% of the 17,690 respondents who provided information about their location.

Conclusion

The EU has invested considerable time and resources in promoting socially responsible research and innovation policies and practices over the last decade. This has resulted in ever-greater demand for measurement frameworks and indicators capable of assessing whether this intervention is delivering improvements in research and innovation systems (e.g., [Heras *et al.*, 2016](#); [Heras & Ruiz-Mallén, 2017](#)). It is important to scale up RRI evaluation to a global level, moving beyond the limited range of considerations and perspectives that define any one world region's approach to developing socially responsible research policies and practices. Relevant to this ambition, the UNESCO-led RSSR ([UNESCO, 2017](#)) establishes formally agreed expectations for national research systems that are well-aligned with RRI principles. Because 195 countries have signed onto this legal instrument, including the requirement for quadrennial monitoring reports, it makes for an excellent vehicle to develop globally relevant RRI indicators. The fact that so many countries are undertaking national assessments relating to RRI on the same timescale, and with the same focus areas, bolsters the potential value of benchmark indicators to be used across multiple countries. Moreover, parallel evaluation of RRI's integration in national research ecosystems on a global scale creates the opportunity for comparative analysis. Such comparative analysis can help to reveal the interventions that most effectively improve RRI policy and practice globally.

Global monitoring and evaluation of RRI-related outcomes is rife with complicated practical and methodological challenges, given the diversity of priorities, interests, resource levels, and capabilities for undertaking measurement exercises in this domain internationally. RRI indicators should be globally relevant, given that science itself is a global enterprise. In addition, it is vital that indicators deliver precise results because they will be used to determine which kinds of RRI policies and practices are most worthy of further investment and development. Methodological rigour is also important to establish a good basis for comparative analyses ([Jensen, 2020a](#); [Jensen, 2020b](#); [Jensen & Lister, 2015](#)), looking across different research and innovation systems to reveal the factors affecting the efficacy of RRI interventions.

This manuscript indirectly addresses the need for methodologically sound measurement approaches for RRI monitoring and evaluation at the level of individual researchers and public opinion. This is because standardised measurement, applied at a regular interval, will likely deliver higher quality data than isolated one-off efforts. Indeed, appropriate methods of monitoring and evaluation are achievable through the application of relevant social research principles:

“Evaluation is just one type of research framework, which focuses on whether a set of objectives have, in fact, been achieved. There is every reason to expect both knowledge and practical guidance to emerge from the same well-designed impact evaluation.” ([Jensen, 2014](#): C04)

Beyond the social research aspect of evaluation, however, the practicalities of implementing an indicators framework inevitably affect methodological rigour. Who will ensure that indicator data are collected? How will the quality of that data be assured? What will motivate nations or organisations to collect, collate, analyse and report such data? This manuscript offers an indicators framework that comes with practical solutions to these challenges for addressing the public opinion and individual researcher level of measurement ([Jensen, 2022b](#)). The proposed use of a range of relevant data sources containing global researcher survey data provides an opportunity for methodological triangulation between different surveys and question types. These international survey data sources (and others) can be used to compare results between countries with the aim of identifying good practices worthy of wider implementation.

If the type of international surveys noted in this essay are used, then opportunities for useful empirical insights emerge that can reflect back on RRI's conceptualisation itself. To effectively mobilise evidence-based practice in the context of RRI, a wider community of international research policy, practice and evaluation must emerge to bring diverse perspectives into dialogue (e.g., see [Jensen & Gerber, 2020](#)). Such efforts can greatly enrich the RRI monitoring and evaluation process by taking into account the different socio-historical and cultural characteristics of each country.

The rationale for introducing high quality public indicators to monitor RRI globally is to enable evidence-based practice in the field of socially responsible research and innovation ([Jensen, 2014](#); [Jensen & Gerber, 2020](#)). Without high-quality measurement in place ([Jensen & Laurie, 2016](#)), it is difficult to accurately pinpoint the policies that are effective in developing healthier research and innovation ecosystems (cf., [Lindner, 2016](#)). Moreover, flying blind without such measurement increases the risk that well-intentioned but ill-conceived RRI policy and practice interventions that have a negative impact in practice go undetected, unchecked and unreformed.

This manuscript provides a concrete proposal of survey questions that can be used to measure key aspects of socially

responsible research and innovation at the level of public opinion. This level of measurement is important, given that the public ultimately provides funding and political support for long-term research and innovation funding from the government, and should be a major downstream beneficiary of research and innovation. The advantage of these particular questions is that they already have data available across many countries and/or have been put through methodological testing to ensure that they are robust. These survey questions are being offered up to start a wider conversation about how best to evaluate progress in the development of healthy and socially responsible research systems. Further development and refinement of the framework presented in this essay will certainly be needed. The long-term journey towards socially responsible research and innovation systems will benefit from such improvements to monitoring and evaluation methods.

With regard to the presentation of a persuasive argument supported by evidence, the references supplied suggest a broad base of reading into, as well as some significant contributions to, the available literature on the topic.

As far as my personal knowledge of the current literature goes, discussion points appear well supported.

The final review question: 'Does the essay contribute to the cultural, historical, social understanding of the field?' is far-reaching in its focus and the debate is in a formative phase.

As a reviewer who is not an academic, my knowledge of the discipline is limited and my opinion is based more on experiential learning and experience in various contexts since the early 1980s first as a teacher, then museum educator and in the past 18 years consolidating that experience and applying it as a science communicator. Historically, it appears that the period covered by this article goes back only as far as the UNESCO-led RSSR (2017), although some of the survey information used was gathered prior to this (2014). It depends how far reaching this essay wants to be in its historical scope, but it could be informative to remember that museums and science centres have been grappling with ways to improve public understanding of science through interpretative design and the use of suitable language in interactive displays and exhibitions at least since the late 1980s.

Whilst the terminology has changed and RRI is now used (to a degree) to capture the idea of the social relevance and applicability of research and innovation, a return to some of the earlier literature regarding living museums and the development of interpretative frameworks to enable more effective engagement with public audiences may be useful in developing meaningful indicators for a broad spectrum of policies and practices.

Similarly, whilst the essay mentions the need for "globally relevant and usable indicators", it does

not make clear reference to indigenous knowledge systems (IKS), which in third world and developing countries are beginning to be sought out and integrated into research and innovation. Perhaps the integration of IKS into RRI and contributions of RRI policies and practices to sustainable development could become indicators in their own right.

Is the topic of the essay discussed accurately in the context of the current literature?

Yes

Is the work clearly and cogently presented?

Yes

Is the argument persuasive and supported by appropriate evidence?

Yes

Does the essay contribute to the cultural, historical, social understanding of the field?

Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: As stated in my report, as reviewer who is not an academic, my knowledge of the discipline is limited and my opinion based on experience in various contexts since the early 1980s as a teacher, museum educator and science communicator.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

This paper does not 'read well' and jumps between ideas without discussion, preamble or context. It is unclear how the paper goes beyond the state of the art despite the author's assertions, and the current state of the art is not described or discussed. There is little discussion or critique, and the paper does not adequately discuss benchmark survey data in the context of making recommendations to evaluate processes that utilise RRI at its core. The abstract mentions a

framework but does not provide a recognisable framework or approach within the paper itself.

The whole premise is the importance of evaluation of RRI practices and policies, but the paper fails to provide context, core principles of RRI or to reference key authors in the field such as von Schomberg, Owen, Stilgoe, Stahl, etc.

A key criticism is that the author draws much of their perspectives from their own published work and therefore does not draw adequately on the wealth of discourse and literature currently available.

The paper assumes that RRI should be deployed in a global context but provides little justification, and does not consider the global implications of implementing a fundamentally Euro-centric framework – given that the UNESCO RSSR referred to throughout this essay states an aim towards a set of ‘shared values’, it is difficult to reconcile this with the inference that those shared values should, by the nature of RRI, be European in nature. The essay does allude to challenges of different and competing national research agendas but offers no explanation of these differences nor competition/competitiveness.

There are also some inconsistencies and inaccuracies. For example, the author states RRI is integral to the RSSR policy instrument and “linking RRI to the 2017 Recommendation”. However, later they take the position that the author-defined 10 key priority areas, “identified and agreed by UNESCO Member States” i.e., the RSSR Policy instrument, should be used to evaluate the development of RRI principles. However, Annex II, Item 7.4 of the agenda of the 37th UNESCO session, (Paris 2017), makes no mention of these 10 priority areas in its 48 recommendations over seven sections. Further, the enshrinement of ‘aspects’ of RRI in the RSSR is contestable as Annex II Recommendation on Science and Scientific Researchers of the General Conference of UNESCO (pp117-127), makes no specific mention of RRI. The basis for recognition or understanding of “the principles included in the RSSR,” by the public, (layman), deemed “not well established” is not justified, and the essay argues for an indicator framework to monitor or measure such a perspective, but does not indicate how such an exercise will offer “specific ways to improve on existing RRI indicators”.

The paper is somewhat situated in current discourses of the literature although it takes a contrary position. For example, its advocacy for “good metrics to measure progress” contradicts, without argument or justification, a Global Research Council (2021) finding of “a shift away from reliance on metrics towards more qualitative or mixed-methods modes of assessment” amongst the global signatories to responsible research assessment ([GRC Publications | Global Research Council](#)). Furthermore, the author’s recommendation for the use of “existing metrics” to save resources and improve quality is unfounded.

The essay engages with a number of surveys around the topic of RRI indicators, although it is not possible to access the linked data and the checklist icon does not highlight any questions and provides no guidance to the reader to parts of the document likely to be most relevant.

The surveys take a diversity of approaches, but it is unclear how much overlap there is between the countries/regions covered, and whilst this is an important issue to address, without understanding which group/country/demographic each survey was tailored to, it is difficult to assess the use of these in the context of the 195 UNESCO RSSR signatories.

From a preliminary view, it appears that European countries feature (somewhat unsurprisingly) heavily in the selected public opinion surveys on RRI progress, and the suitability and/or effectiveness of these surveys being translated globally is ill-explored here.

Justification for the selection of the six sources of global survey data are absent, as are explanations of its relevance either to RRI or RSSR. Why just the six (at public level)? It is notable that whilst the WGM is relied upon as 'truly global', the author does not clarify that the 2020-21 survey covered a reduced scope of 113 countries, rather than the 140+ countries in the 2018 version – given 195 countries signed up to the UNESCO RSSR, this does not, in fact, feel 'truly global'. Further, the use of the 2014 Eurobarometer report feels outdated, given the development of approaches to (and measures of) RRI since then.

In the section on individual researcher level of measurement, the author fails to note that the UNESCO formal national reporting it is left up to the member states themselves to determine 'the criteria for inclusion in the category of persons recognized as scientific researchers', making global indicators for this category difficult to compare.

The essay seeks to monitor public and researcher perspectives but makes no justifiable case for establishing the rationale. Equally, it is quite unclear as to the "progress" of what is monitored by the "high-quality indicators": researcher perspectives or impacts of (the UNESCO) policy instrument or indeed its use to "benchmark the development of socially responsible research and innovation".

To pass peer review, this paper will require considerable revision to include a comprehensive review of current literature across all aspects of the paper's topic, and to provide justification and explanation of the ideas presented. The paper should also be re-structured to provide a narrative that guides the reader through the paper, and provides evidence-based conclusions.

Is the topic of the essay discussed accurately in the context of the current literature?

No

Is the work clearly and cogently presented?

No

Is the argument persuasive and supported by appropriate evidence?

No

Does the essay contribute to the cultural, historical, social understanding of the field?

No

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: All three reviewers work in the area of computer and technology ethics and have strong backgrounds in RRI.

We confirm that we have read this submission and believe that we have an appropriate level

of expertise to state that we do not consider it to be of an acceptable scientific standard, for reasons outlined above.

Operationalising Responsible Research and Innovation paradigm is a necessary step towards the maturity of this concept. Some progress has already been made in this area - more with regard to public entities (research institutes, higher education institutions, funding agencies), less with regard to industry (enterprises, private labs).

The submitted essay looks at the possibility of developing a framework (a set of indicators) to monitor progress toward the socially responsible innovation at the global level, from the perspective of the public and individual researchers. Author proposes to make use of the already existing vehicle of the 2017 UNESCO-led Recommendation on Science and Scientific Researchers (RSSR). As such, this proposal is rational and offers an approach that addresses a frequent problem of "reinventing the wheel".

Since this is an essay, I recommend that the Introduction is supplemented with an explanation/definition of socially responsible research and innovation. The main body of the text consists of short descriptions of various data sources/surveys that, according to the author, may be linked to socially responsible research and innovation. The attempt to link particular surveys to specific aspects/dimensions of RRI is desirable. It would indicate clearly how a particular survey/dataset is linked to the concept of RRI. Moreover, some sort of a concise synthesis of all presented surveys would be helpful. What RRI dimensions are covered? What dimensions are not yet covered?

The chosen form of the submission (essay) imposes a certain discipline on the author. One has to present thoughts in a coherent and non-trivial way, without pondering on details and nuances in order to keep the text short. The author has been successful to this end.

Eight out of 13 referenced works are the author's own publications. That would be a problem with a research paper but is acceptable in an essay, especially given that the references are relevant.

Is the topic of the essay discussed accurately in the context of the current literature?

Yes

Is the work clearly and cogently presented?

Yes

Is the argument persuasive and supported by appropriate evidence?

Partly

Does the essay contribute to the cultural, historical, social understanding of the field?

Yes

Competing Interests: No competing interests were disclosed.
