# Radical aromatic cyclisation and 

## substitution reactions

## By

## Nicholas Patrick Murphy

A thesis submitted in partial fulfillment of the requirement for the degree of Doctor of Philosophy in Chemistry

University of Warwick, Department of Chemistry

|  | CHAPTER TWO-RADICAL REACTIONS OF $\boldsymbol{N}$-BUTYL-(SUBSTITUTED)-ARYLSULFONAMIDES | 73 |

1.0 Introduction ..... 74
1.1 Aims and Objectives ..... 75
2.0 Synthesis and use of sulfonamide starting materials ..... 75
2.1 Synthesis and use of the radical precursor 278 ..... 77
3.0 Synthesis of the amine ligand-TPA 279 ..... 81
3.1 Reaction of parent compound 278a with copper (I) salt/TPA ..... 81complex
3.2 Purification of the radical products ..... 83
3.3 Characterisation of cyclised material 287 ..... 83
3.4 Potential mechanism for oxindole formation ..... 86
4.0 Use of tosyl sulfonamide 278e and mechanistic insights into ..... 98oxindole formation
4.1 Introduction ..... 99
4.2 Proposed methods for separation of regioisomers ..... 101
4.3 Radical reaction of tosyl precursor 278e ..... 103
4.4 Attempted synthesis of the major oxindole 336 ..... 104
4.5 Authentic synthesis of the rearranged amide 280e ..... 105
4.6 Reaction of tosyl substrate 278e in various solvents ..... 107
5.0 $\quad N$-Butyl-2,4,6-trimethyl-benzenesulfonamide 281f ..... 109
6.0 $\quad N$-Butyl-2-naphthylsulfonamide 278g ..... 110
7.0 $\quad N$-Butyl-4-methoxy-benzenesulfonamide 278h ..... 111
8.0 Effects of different halogens in the para position ..... 114
8.1 The fluoro radical precursor 278b ..... 114
8.2 The bromo and iodo radical precursors 278 c -d ..... 116
9.0 Effects of para and meta electron-withdrawing groups ..... 117
9.1 The cyano and nitro radical precursors 278i-j ..... 118
9.2 The trifluoromethyl and meta-3,5-trifluoromethyl radical ..... 122 precursors 278k-1
10.0 Conclusion for chapter two ..... 125
11.0 Future work ..... 126
CHAPTER THREE RADICAL REACTIONS OF $N$ - ..... 127ALKYL/(ARYL-4-METHYL-BENZENESULFONAMIDES1.0 Aims and Objectives128
1.1 Synthesis of radical precursors ..... 128
1.2 Current synthesis of radical precursors ..... 130
2.0 Reaction of $N$-alkyl 4-methylbenzenesulfonamide with copper ..... 132
(I) bromide and TPA
2.1 Current work ..... 132
2.2 Reactions in other solvents ..... 136
2.3 Other reactions ..... 138
2.4 Effects of dichloromethane at room temperature on product ..... 139 distribution
3.0 Synthesis of $N$-(hetero)aromatic radical precursors 380a-i ..... 141
3.1 Synthesis of radical precursors ..... 143
3.2 Attempted radical reaction of (hetero)aromatic sulfonamides ..... 144
381
4.0 Conclusion for chapter three ..... 147
CHAPTER FOUR REACTIONS OF $N$-ETHYL- $N$ - ..... 150TRICHLOROACETYL-4-METHYLBENZENE-SULFONAMIDE AND HALO-AMIDES WITH CUX/TPA
1.0 Introduction ..... 151
1.1 Investigation of the trichloroacetamide substrate 398 ..... 151
1.2 Radical reaction of the trichloroacetamide 396 ..... 153
2.0 Synthesis of oxindoles from halo-amides ..... 154
2.1 Synthesis of precursors 409-411 ..... 155
2.2 Reactions of radical precursors 278e, 409-411 ..... 156
2.3 Additional reactions ..... 157
3.0 Conclusions for chapter four ..... 158
4.0 Future work ..... 159
CHAPTER FIVE EXPERIMENTAL ..... 160
1.0 General ..... 161
1.1 General synthesis of N -butyl-(substituted)-aryl sulfonamides ..... 162
1.1.1 Method A ..... 162
1.1.2 Method B ..... 163
$N$-Butyl-benzenesulfonamide ..... 283a ..... 163
$N$-Butyl-(4-fluoro)-benzenesulfonamide ..... 283b ..... 163
4-Bromo-( $N$-butyl)-benzenesulfonamide ..... 283c ..... 164
$N$-Butyl-(4-iodo)-benzenesulfonamide ..... 283d ..... 165
$N$-Butyl-4-methylbenzenesulfonamide ..... 283e ..... 165
Naphthalene-2-sulfonic acid-butyramide ..... 283g ..... 166
$N$-Butyl-(4-methoxy) benzenesulfonamide ..... 283h ..... 167
$N$-Butyl-(4-cyano)-benzenesulfonamide ..... 283i ..... 167
$N$-Butyl-(4-nitro)-benzenesulfonamide ..... 283j ..... 168
$N$-Butyl-(4-trifluoromethyl)-benzenesulfonamide ..... 283k ..... 169
$N$-Butyl-(bis-3,5-trifluoromethyl)-benzenesulfonamide ..... 2831 ..... 169
2.0 General synthesis of $N$-alkyl-substituted 4- ..... 170
methylbenzenesulfonamide
2.1 Method A ..... 170
2.2 Method B ..... 170
$N$-Ethyl-4-methylbenzenesulfonamide ..... 374a ..... 171
$N$-Propyl-4-methylbenzenesulfonamide ..... 374b ..... 171
4-Methyl- $N$-pentyl-benzenesulfonamide ..... 374d ..... 172
N -Hexyl-4-methylbenzenesulfonamide ..... 374e ..... 173
$N$-Docecyl-4-methylbenzenesulfonamide ..... 374f ..... 173
N -iso-Propyl-4-methylbenzenesulfonamide ..... 374g ..... 174
N -iso-Butyl-4-methylbenzenesulfonamide ..... 374h 175
N -sec-Butyl-4-methylbenzenesulfonamide ..... 374i ..... 175
$N$-tert-Butyl-4-methylbenzenesulfonamide ..... 374j 176
$N$-(R)-(-)-1-Cyclohexylethyl-4-methylbenzenesulfonamide ..... 374k 177
N -Adamantan-1-yl-4-methylbenzenesulfonamide ..... 374I ..... 177
3.0 General synthesis of N -(hetero)aromatic substituted-4- ..... 178 methylbenzenesulfonamide

| 3.1 | Method A |  | 178 |

### 0.3 Acknowledgements

I would like to express my thanks to my Supervisor Dr Andrew Clark, for giving me this excellent opportunity to pursue this major part of my career, in addition all advice and help is appreciated. In particular, I would like to express my sincere gratitude to the EPSRC for their financial support, without whose help; this PhD would not have been possible. I would also like to express my thanks to Dr Paul Taylor and Professor Martin Wills for their advice during the first and second year viva-voca examinations. I also acknowledge the technical team at Warwick University, MEDEC from Exeter for the CHN/ sulfur analysis, and especially to Peter from the glassblowers for all his help. I would like to express my thanks to Dr Stuart Coles for all his helpful discussions, and Dr Jake Irwin. Also to Rob Jenkins on technical discussions. To many good colleagues from the Shipman, Taylor and Wills group who came to the Fifth floor Coffee Room.

For recreation, there was the Art Centre and Xananas- Most of my mates went to Xananas, and I found it a good place to chill out. To the Language Society and especially the truly wonderful people I met at Mass in the Chaplaincy on Sundays. My favorite place was Leamington, and I enjoyed living there from 2004-2006. I am very happy to have met some genuinely nice people-all the Greeks for your hospitality.

I am very grateful to Professor Martin Wills and Professor Keith Jones for their advice during the PhD Viva. Since resubmitting the Thesis, I would like to express my thanks to the many organizations that have made pursuing my research possible. The Royal Society of Chemistry Library, the Imperial College Library and the British Library, and
librarians who have been helpful. I would like to express my sincere gratitude to Dr John Storey and Dr Andrew Clark for proofreading the revised Thesis.

This PhD would not be complete without mentioning all those who have helped me in the past. I would like to express my thanks especially to Lloyd Vidale who first taught me Chemistry and encouraged me to go to University. At Kingston, I would like to express my thanks to Dr Cooper who was my Industrial Supervisor in 1998. To Dr Buckley-Dhoot for all her help and especially to Dr John Storey who was my third year supervisor. In addition, special thanks to Dr Klaus Jürgen Pees and Pieter Liers at Schwabenheim. I dedicate this work to my parents, brother and sister and my nieces. Also to all who have given me, support to be here.

## 0.4 Declaration

The work described in this thesis is the original work of the author, except where acknowledgement has been made to results and ideas previously reported. The work was carried out in the department of chemistry, University of Warwick between August $1^{\text {st }}$ 2003 and September 4th 2006 and has not been previously submitted for a degree at any other institution.

### 0.5 Abstract

This dissertation is divided into five chapters. Chapter One consists of an introduction to radical cyclisation and rearrangement reactions. Chapter Two investigates the reactions of substituted arylsulfonamides 278a-I with copper bromide and an amine ligand-TPA. This reaction involves an alkyl radical generated from the copper (I) bromide/TPA complex, which can then undergo a 1,5 - ipso attack onto the sulfonamide leading to a cyclohexadienyl radical intermediate. Re-aromatisation and extrusion of sulfur dioxide leads to an amidyl radical intermediate. This can undergo either cyclisation back onto the aromatic ring to give the 6 -substituted oxindole 336, or reduction from H -atom abstraction by the solvent leading to rearranged amides. A minor product identified as a 5-substituted oxindole $\mathbf{3 3 3}$ may be formed from direct radical cyclisation onto the sulfonamide followed by extrusion of sulfur dioxide. An unambiguous synthesis of $\mathbf{3 3 3}$ was obtained through the Stollé method in order to rigorously identify this product. For completion, the rearranged amide 280e was also unambiguously synthesised from known literature sources. It has been shown that the selectivity towards either rearrangement or cyclisation is dependent upon the solvent used and temperature. For example, toluene induces excellent selectivity towards cyclisation (to furnish oxindoles), while using dichloromethane (DCM) induces a greater selectivity towards rearranged amides. Chapter Three explores the effects of varying the alkyl chain length on the nitrogen atom on selectivity, while keeping both the aryl group and initiator the same. It has been shown that selectivity towards the rearrangement (or decrease in cyclisation) occurred when the alkyl chain was increased from $N$-butyl to $N$-dodecyl. In addition a similar solvent effect on selectivity was observed as discussed in Chapter 3, notably relatively more rearranged amide was produced with DCM and oxindoles with toluene.

Chapter four involves investigating the copper-mediated radical cyclisation of haloamides to give oxindoles directly. The final chapter consists of the experimental.

## LITERATURE REVIEW

## Chapter One

### 1.0 Introduction to radical chemistry

Radicals are defined as chemical species that contain one or more unpaired electrons. Amongst the several types of radicals known to the chemist, it is the carbon-centred radical, which has received the most attention. This has been particularly the case in reactions involving the formation of new $\mathrm{C}-\mathrm{C}$ bonds, such as polymerisation reactions, ${ }^{1}$ and the construction of cyclic compounds. ${ }^{2-4}$ The use of nitrogen, ${ }^{5}$ phosphorus ${ }^{6}$ or sulfur-based ${ }^{7-8}$ radicals are less common in synthesis, yet there has been extensive research in these areas.

The majority of carbon based alkyl radicals (eg. $\cdot \mathrm{CH}_{3}$ ) are trigonal planar in structure (similar to carbocations), although some exceptions are possible. When hydrogen atoms on a methyl radical are replaced by an $\sigma$-attractor, $\pi$-donor component or group (halogen, $\mathrm{OH}, \mathrm{NH}_{2}$ ) this leads to pyramidalization of the radical. In the case of $\cdot \mathrm{CF}_{3}$, this results in a tetrahedral structure. ${ }^{9}$ The $s p^{2}$-hybridized atom is electron deficient, and as such, the stability of the radical is increased with substitution of alkyl groups, hence tertiary alkyl radicals are stabilized more than secondary ones. Resonance is also a contributing factor in radical stability. ${ }^{2}$

### 1.1 Classes of radical reactions

Radicals can undergo a range of reactions, for example abstraction (eq. L) ${ }^{10}$ intermolecular addition (eq. $\underline{2})^{11}$ intramolecular addition (eq. $\left.\underline{3}\right)^{12}$ rearrangement (eq. 4) ${ }^{13}$ and radical-radical reaction (eq. 5$)^{14}$ as outlined in Scheme 1.

## Scheme 1 Possible radical reactions

### 1.2 Radical abstraction reactions

An early example of radical abstraction reactions were those involving the reaction between an alkyl radical and an alkyl halide. Much work was done during the 1960's on these types of reactions. King and Swinbourne ${ }^{15}$ investigated the abstraction of halogen atoms by methyl radicals. Thermal homolytic dissociation of di-tert-butylperoxide $\mathbf{1}$ gives two molecules of tert-butyl peroxide radical $2{ }^{16}$ The tert-butyl peroxide radical 2 formed can then undergo a $\beta$-fragmentation to give a methyl radical $\mathbf{3}$ and acetone. A high temperature $\left(>150^{\circ} \mathrm{C}\right)$ is required to produce the methyl radical 3, since the activation energy is between $6-8 \mathrm{kcal} / \mathrm{mol}$ higher for $\beta$-fragmentation than that of hydrogen abstraction by tert-butyl peroxide radical 2. Reaction of a methyl radical $\mathbf{3}$ and ethyl chloride $\mathbf{4}$ yield both methane 5 and the 1-chloroethyl radical $\mathbf{6}$ as shown in Scheme 2.

## Chapter One

Scheme 2 Hydrogen atom abstraction by methyl radical ${ }^{15}$
Whilst the majority of reactions involve abstraction of hydrogen atoms from alkanes, it is also possible to get abstraction of other atoms attached to an alkyl group. These include radical leaving groups such as $\mathrm{PhS},{ }^{9} \mathrm{PhSe},{ }^{17}$ Barton esters ${ }^{18}$ and xanthates ${ }^{19}$ (which are popular ways to achieve de-oxygenation of alcohols). ${ }^{20}$ Abstraction of atoms other than hydrogen (e.g. halogens) have also been reported. ${ }^{21}$ In this case tributyltin radical abstracts an iodine atom from iodobenzene $\mathbf{7}$ to give an aryl radical $\mathbf{8}$ and tributyltin iodide as depicted in Scheme 3.

## Scheme 3 Halogen abstraction from an aromatic ring

### 1.3 Radical addition reactions

Radicals can add to unsaturated substrates, (such as alkenes, alkynes and aromatic groups) in an inter- and intramolecular fashion.

### 1.3.1 Intermolecular addition

In 1933 a series of reactions by Kharasch, McCabe and Mayo ${ }^{22}$ on the addition of hydrogen bromide $\mathbf{1 1}$ to propylene $\mathbf{1 2}$ were studied. Homolytic dissociation of dibenzoyl peroxide $\mathbf{9}$ at room temperature gave two molecules of benzoyl peroxide radical 10. In the presence of a benzoyl peroxide radical 10, rapid abstraction of the hydrogen

## Chapter One

atom from hydrogen bromide $\mathbf{1 1}$ led to the bromine radical, which could then add to propylene 12. This was followed by formation of a secondary alkyl radical intermediate 13, which underwent hydrogen atom transfer to furnish the anti-Markovikov product 1bromopropane $\mathbf{1 4}$ in $87 \%$ at room temperature, as illustrated in Scheme 4. The regiochemistry of addition in the presence of anti-oxidants was reversed and the Markovnikov product, (iso-propyl bromide, not shown) formed via an ionic (electrophilic) addition resulted.

## Scheme 4 Radical bromination of an alkene ${ }^{22}$

### 1.4 Intramolecular addition reactions (cyclisations) ${ }^{23-26}$

With the exception of radical polymerisation reactions, intramolecular radical reactions have probably received the most attention. Baldwin's rules ${ }^{27}$ generally govern the regiochemical outcomes of these cyclisations, hence, the 5-hexenyl radical 15 preferentially cyclises to give the 5-exo product $\mathbf{1 6}$ via a chair-like transition state. ${ }^{28}$ The reactions are normally under kinetic control and as such the major product is the five membered ring in the ratio of $98: 2(\mathbf{1 6 : 1 7})$ at room temperature for the all carbon case as illustrated in Scheme 5. Cyclisation onto alkynes ${ }^{29}$ and aromatics are also possible (see Section 2.0).

## Chapter One

Scheme 5 5-Hexenyl radical cyclisation

### 1.5 Radical rearrangements

A range of radical rearrangement (or migration) reactions has been reported where either atoms or groups of atoms, can undergo migration. A classic example is the 1,2-phenyl migration ${ }^{30}$ of radical 18 (Scheme 6). The migration is thought to occur via 3-ipso-exo cyclisation onto the aromatic ring to furnish the spirocyclised radical intermediate 19 followed by reversible ring opening via cleavage of the alternative $\mathrm{C} / \mathrm{C}$ bond to yield the iso-butyl benzyl radical 20 .

## Scheme 6 Possible radical rearrangement reaction

### 1.5.1 Group transfer reactions

Urry and Kharasch explored neophyl rearrangements in $1944 .{ }^{31}$ These are 1,2migrations ${ }^{32}$ typified by the reaction shown in Scheme 7. Groups that undergo this type of migration include nitrates ${ }^{33} \mathbf{2 2}$, phosphate, ${ }^{34}$ ester ${ }^{35}$ and sulfonate derivatives. ${ }^{33}$ The driving force for such reactions is often the formation of a more stable radical (i.e. the primary radical 21 was transformed to the secondary benzylic radical $\mathbf{2 2}$ as depicted in

## Chapter One

Scheme 7. O-Neophyl rearrangement of 1,1-diarylalkoxyl radicals have also been reported. ${ }^{36}$ These sorts of migration can also occur in vivo, normally mediated by vitamin $\mathrm{B}_{12}$ and cobalt dependent enzymes. ${ }^{37}$

Scheme $7 \quad$ An 1,2-aryl migration

### 1.5.2 Hydrogen abstraction reaction

Other rearrangement can occur via hydrogen abstractions. A range of H -abstraction reactions have been reported (eg. 1,2-;, ${ }^{38} 1,4-;{ }^{38} 1,5-{ }^{39}{ }^{39} 1,6$-, $\left.{ }^{40} 1,7-;\right)^{41}$ However the commonest are $1,5-\mathrm{H}$ abstraction which occur via a chair-like transition state. For example, peroxide-initiated radical abstraction of the iodo compound 23 (Scheme 8) yielded the alkyl radical intermediate 24. This then underwent a $1,5-\mathrm{H}$ abstraction, to give 25 which was terminated by abstraction of an iodine atom to furnish the iodosulfone $\mathbf{2 6}$ in $94 \%$ yield. ${ }^{39}$

Scheme 8 An 1,5-H abstraction from alkyl iodide
Hydrogen abstractions can also occur from aromatics. ${ }^{42}$ Irradiation of an iodobenzophenone 27 (Scheme 9) in tert-butanol furnished the aryl radical intermediate 28, which then underwent 1,5-hydrogen abstraction to give the new radical 29 .

## Chapter One

Scheme 9 An 1,5-H abstraction from an iodo aromatic compound ${ }^{42}$ In another example, Curran ${ }^{43}$ has treated an ortho-halo-aromatic 30 (Scheme 10) with tributyltin hydride/AIBN to form the aryl radical intermediate 31, which underwent an 1,5-H atom abstraction to furnish the alkyl radical intermediate 32.

Scheme 10 An 1,5-H abstraction from an aryl radical to form an alkyl radical

### 1.6 Radical-radical reactions ${ }^{3,9}$

The process in which two radical species interact to form non-radical products is called chain termination. Two processes are possible: (1) radical coupling and (2) disproportionation. In the following example, the methyl radical $\mathbf{3}$ and ethyl radical $\mathbf{3 3}$ re-combine to give the radical coupled product propane $\mathbf{3 4}$ or through disproportionation to furnish methane $\mathbf{5}$ and ethylene $\mathbf{3 5}$ as depicted in Scheme $\mathbf{1 1}$ When two of the same radical fragments re-combine, this is called dimerisation. A classic example is the Kolbe ${ }^{44}$ aniodic oxidation of carboxylic acid salts.

## Scheme 11 Possible radical coupling and disproportionation reaction

## Chapter One

### 2.0 Aromatic radical reactions-Addition to aromatic ring.

Intermolecular addition onto an aromatic ring ${ }^{45-47}$ can go through three possible mechanistic pathways. These include; (1) aromatic nucleophilic substitution ${ }^{45}$-an attack by a nucleophile ( $\mathrm{Nu}^{-}$), giving an anionic $\sigma$-complex, and loss of an anion; (2) aromatic electrophilic substitution ${ }^{46}$-an attack by an electrophile $\left(\mathrm{E}^{+}\right)$, giving a cationic $\sigma$ complex, and loss of a cation; and (3) aromatic homolytic substitution ${ }^{47}$-an attack by a radical ( $\mathrm{R}^{*}$ ), giving a radical $\sigma$-complex and loss of a leaving group (which is normally hydrogen, $\mathrm{H}^{*}$ ). An early example of an intramolecular homolytic aromatic substitution involves the Pschorr reaction ${ }^{48-50}$ as illustrated in Scheme 12. In this example, the radical precursor 36 when treated with copper (I) chloride furnished the aryl radical 37 through loss of nitrogen gas. This aryl radical can then add into the aromatic ring to give the cyclohexadienyl radical intermediate $\mathbf{3 8}$ followed by re-aromatisation to the tetracyclic product 39.

### 2.1 Introduction ${ }^{51-55}$

The primary objectives of this thesis were to investigate the cyclisation of radicals into aryl rings. Due to the nature of the cyclisation systems involved (discussed in Chapters 2-4) rearrangement reactions compete with the desired cyclisations. Therefore, the remainder of the introduction will focus both on radical cyclisation into aryl rings and radical rearrangement reactions.

## Chapter One

### 2.2 Mechanistic aspects of aromatic homolytic substitution reactions

Historically, homolytic aromatic substitutions have resulted in poor yields and product mixtures. A prime example of this is the Gomberg reaction, ${ }^{56}$ that not only gives every possible regioisomer, but also radical-radical coupling by-products as shown in Scheme 13. In this example, the aryl diazonium salt $\mathbf{4 0}$ when treated with a base ( -OH ), furnishes the aryl radical 41 through loss of nitrogen gas and the generation of a hydroxide radical. The aryl radical $\mathbf{4 1}$ can then add into another aromatic ring 42, which if substituted (Z) could lead to several regioisomers-namely para 43 , meta 44 and ortho 45 radical intermediates, followed by re-aromatisation to give para 46, meta 47 and ortho 48 biaryls. The aryl radical $\mathbf{4 1}$ could also recombine with another aryl radical $\mathbf{4 1}$ to give the dimerised product 49.

## Scheme 13 The Gomberg reaction

## Chapter One

A far more useful variant of this reaction involves intramolecular homolytic aromatic substitution, which will be illustrated later in the thesis. The mechanism of rearomatisation (oxidation) in these substitution reactions is somewhat curious. The first step of the reaction appears logical and straightforward, in that a radical $\mathrm{R} \cdot$ attacks the aryl ring (see Scheme 14) to produce a sigma complex (or cyclohexadienyl radical when the aryl ring is benzene). This intermediate then has to undergo what is formally an oxidation reaction to give the fully aromatic product. The strange feature of the mechanism lies in this re-aromatisation step, since typically these reactions are conducted using $\mathrm{Bu}_{3} \mathrm{SnH}$ as the radical mediator (see Scheme 15), formally a reducing agent. Therefore, it would appear that oxidation is taking place in the presence of a redundant! Several hypotheses have been forwarded to explain this dichotomy over the years.

This process has been extensively reviewed by Bowman and Storey. ${ }^{47}$ The intermolecular reaction proceeds via a sigma ( $\sigma$ ) complex intermediate $\mathbf{5 0}$ as illustrated in Scheme 14, followed by extraction of the leaving group and re-aromatisation. ${ }^{57}$ The mechanism for the re-aromatisation will depend upon the reaction conditions employed, and the leaving group X .

50

## Scheme 14 Homolytic aromatic substitution-mechanistic outline

## Chapter One

Intermolecular addition reactions of the type outline in Scheme $\mathbf{1 4}$ have been previously investigated. Traynham ${ }^{58}$ has conducted mechanistic studies on the effects of substituents on the aromatic ring (ipso substitution).

### 2.3 Alkyl radical cyclisation onto aromatics

While cyclisation of alkyl radicals onto unsaturated systems (e.g. alkenes, see Section 1.4), abound in the literature, there are relatively few examples of cyclisation of such radicals onto aromatic rings (Scheme 15). In these reactions, there is direct attack onto the aromatic ring, from the nucleophilic alkyl radical followed by re-aromatisation. The mechanism of this re-aromatisation will depend upon the reaction conditions.

Scheme 15 General mechanism for intramolecular cyclisation
The uses of aryl halides ${ }^{59-60}$ as substrates to initiate cyclisations onto monoaromatics have also been investigated. Beckwith and Storey ${ }^{60}$ has shown that the precursor 51 when treated with tributyltin hydride and AIBN in toluene led to the aryl radical $\mathbf{5 2}$ that could undergo an 1,5-hydrogen atom transfer to furnish the newly stabilised tertiary radical 53. This was followed by aromatic homolytic substitution leading to the cyclohexadienyl radical intermediate $\mathbf{5 4}$ to give the oxindole $\mathbf{5 5}$ in $81 \%$ yield as depicted in Scheme 16.

## Chapter One

Scheme 16 Synthesis of a spirocyclic oxindole ${ }^{60}$
Three possible mechanisms for re-aromatisation have been postulated; (1) oxidation of 54 by AIBN as mentioned by Curran. ${ }^{61}$ (2) disproportionation of $\mathbf{5 6}$ followed by oxidation of the cyclohexadienyl radical intermediate during work-up. In this illustrative example (Scheme 17); the re-aromatisation process occurs as follows; one molecule of the aryl radical intermediate $\mathbf{5 6}$ abstracts a hydrogen atom from another molecule of the aryl radical intermediate 56 leading to the re-aromatised product 58 and the cyclohexadienyl radical intermediate 57 , which upon oxidation would furnish the bicyclic product 58.

Scheme 17 Disproportion reaction

## Chapter One

The third possibility invokes a mechanism involving the intervention of the initiator fragments, and later proven by Beckwith, Storey and Bowman as illustrated in Scheme 18. By using the fully deuterated aromatic substrate 59 the production of the deuterated initiator fragment $\mathbf{6 0}$ was proven. However, it would appear, at least in the system investigated that other mechanistic pathways were operating at the same time.

## Scheme 18 Investigation of re-aromatisation using deuterated arenes.

Until recently the mechanism proposed by Bowman ${ }^{62}$ was generally accepted as an adequate explanation for oxidation in $\mathrm{Bu}_{3} \mathrm{SnH}$ mediated reactions. This involved $\mathrm{Bu}_{3} \mathrm{SnH}$ acting as a hydride donor and radical $\mathbf{6 1}$ acting as a protic acid to give the arene radical anion 62. This is then postulated to undergo a single electron transfer (SET) to the starting halide to maintain the chain process as shown in Scheme 19.

## Scheme 19 Bowman's hypothetic mechanism for re-aromatisation

## Chapter One

More recently a thorough investigation of the mechanism of general re-aromatisation under different conditions has been published. ${ }^{57}$ Each mechanistic possibility has been investigated and it would appear that the radical initiator is the key to determining the mechanism.

Two parallel mechanistic pathways were proposed. The first, involving an initiator fragment (resulting from AIBN homolysis) as outlined below. Under the conditions of the reaction investigated this would appear to be the minor mechanism. The major mechanism appears to involve the initiator acting as an oxidising agent prior to homolysis. These two competing mechanistic pathways are illustrated in Scheme 20. It would appear from the results presented that the postulation of each pathway is highly dependent upon the substrate, initiator, radical mediator and other reaction conditions.

Scheme 20 Bowman and Storey proposed mechanism for re-aromatisation

## Chapter One

Storey has applied this methodology to the synthesis of aza-oxindoles ${ }^{63}$ In addition to tributyltin hydride as a radical carrier or radical mediator, other reagents have also been employed to furnish carbocyclic and heterocyclic compounds. These cyclisations can be carried out with a combination of TTMSS/AIBN. Further evidence suggesting the role of the initiators involvement in re-aromatisation can be seen in the synthesis of methoxybenzene derivatives as well as with other reagents. ${ }^{64}$

### 2.3.1 Cyclisation of xanthates

(S)-Aryl ether xanthates 63 was treated with dilauroyl peroxide, and the alkyl radical 64 was produced (Scheme 21). ${ }^{65}$ This then cyclised to give a mixture of products. Interestingly, radical cyclisation via path A predominates leading to the (S) 3aminochromane with the substituent in the 5-position 66. Radical cyclisation via the cyclohexadienyl radical intermediate 67 (path B) led to the (S) 3-aminochromane with the ketone substituent in the 7-position 68 . Re-aromatisation under these xanthatemediated conditions was postulated to go through a single electron transfer-SET process as described by Zard, ${ }^{66}$ however, it would seem feasible, that the lauroyl radical could abstract the hydrogen atom from intermediate $\mathbf{6 5}$ or $\mathbf{6 6}$ to produce re-aromatisation.

## Chapter One

## Scheme 21 Guillaumet synthesis of aminochromane ${ }^{65}$

However, several inconsistencies in this work were observed. It was stated that the iodo compound 63a gave the best overall yield ( $37 \%$ for 66); yet, it is evident that it is the xanthate compound 63b that has the highest yields (69\%) for the aminochromanes 66.

Similarly, $\alpha$-tetralone derivative 73 have also been synthesised using an alkyl radical cyclisation ( $48 \%$ ). Zard $^{67}$ investigated the radical addition of acetophenone xanthate $\mathbf{6 9}$ onto vinyl pivalate 70 in the presence of dilauroyl peroxide (DLP) to give the radical adduct 71 (scheme 22). This alkyl radical 71 then underwent cyclisation onto the aromatic ring leading to $\mathbf{7 3}(48 \%)$, after re-aromatisation of $72 .{ }^{68-70}$ No mechanistic hypothesis was presented for re-aromatisation, but again, the initiator, dilauroyl peroxide is required in stoichiometric quantities in order to obtain reasonable yields of product. This would strongly suggest that the initiator is involved with the re-aromatisation process as previously discussed.

## Chapter One

## Scheme 22 Zard's synthesis of $\boldsymbol{\alpha}$-tetralone ${ }^{67}$

### 2.4 Sequential intermolecular/intramolecular radical cyclisation onto aromatics

The use of an initial intermolecular addition to generate a new radical that is suitable for cyclisation into aromatics has been achieved. This methodology has been used in the synthesis of heterocycles and provides an elegant method for the generation of a cyclisation precursor radical. $N$-allyl-anilides 74 were treated with the 'Tordo alkoxyamine' $75 .^{71-73}$ Thermal homolysis of $\mathbf{7 5}$ led to the formation of an alkyl radical 76 and a nitroxyl radical ("SG1") 77. Radical addition of 76 to the alkene generated the more stable radical intermediate 78, followed by intramolecular addition onto the aromatic ring to furnish the cyclohexadienyl radical intermediate 79, which upon rearomatisation furnished the indole product 80 in $63 \%$ yield as shown in Scheme 23. No evidence of products produced from the trapping of the radical intermediate 79 was observed. It was assumed that re-aromatisation arose either from H -atom abstraction by the nitroxide radical or because of its initial re-combination with SG1 77 followed by elimination to furnish $\mathbf{8 0}$. No mechanistic evidence is presented for either pathway.

## Chapter One

Scheme 23 Tordo's synthesis of indole ${ }^{71}$
The same method was used in synthesising oxindole 82. The nitroxide radical ${ }^{74}$ ("SG1")-tethered substrate $\mathbf{8 1}$ underwent aromatic homolytic substitution and rearomatisation to furnish $\mathbf{8 2}$ in 63\% yield as depicted in Scheme 24.

Scheme 24 Synthesis of $N$-methyl-3,3-dimethyloxindole
Carbocycles can also be produced via intramolecular addition (Scheme 25). Addition of a tosyl radical $\mathbf{8 4}$ onto the terminal alkene $\mathbf{8 3}$ furnished the more stable secondary alkyl radical intermediate $\mathbf{8 5}$, which could undergo cyclisation onto the aromatic ring leading to the cyclohexadienyl radical intermediate 86 . Oxidation of $\mathbf{8 6}$ by subsequent reaction with copper acetate furnished the tetrahydronaphthalene $\mathbf{8 7}$ in $90 \%$ yield. ${ }^{75}$ In this case the oxidation by $\mathrm{Cu}^{2+}$ gives the cyclohexadienyl cation (not shown), which loses a proton generating acetic acid and $\mathrm{Cu}^{\mathrm{I}}$. When the reactions were carried out under acidic

## Chapter One

conditions (acetic acid), high yields were obtained ( $90 \%$, 48h), when formic acid was used, the reaction was accelerated $82 \%$, (9h).

## Scheme 25 Synthesis of carbocyclics ${ }^{75}$

A less common sequential approach to heteroaromatics via cyclisation onto an aryl group is the intermolecular-intramolecular reactions of benzylideneamines. Thermal homolytic dissociation of diisopropyl peroxydicarbonate (DPDC) ${ }^{9}$ (2 equivalents) $\mathbf{8 8}$ in benzene at $60^{\circ} \mathrm{C}$ gave the isopropyloxycarbonyl radical $\mathbf{8 9}$ which could then abstract a hydrogen atom from N -benzylidineamine $\mathbf{9 0} .^{24}$ Addition of this radical to the alkyne, $\mathbf{9 1}$ was maintained until complete consumption of the radical initiator 89. This then gave the vinyl radical intermediate $\mathbf{9 3}$ which subsequently underwent cyclisation into the aryl ring to yield the quinoline derivatives $\mathbf{9 4}$ as depicted in Scheme 26. Similar approaches to Luotenin $A^{47}$ have shown that re-aromatisation occurred from hydrogen abstraction of the intermediate cyclohexadienyl radical intermediate by a methyl radical generated from the breakdown of $\mathrm{Me}_{3} \mathrm{Sn} \bullet$ radicals or tert-butoxyl radicals. In this example, a high concentration of hexamethylditin was required (14 equivalents) to furnish the product. This could explain how the step from 93 to 94 was achieved. In that case it would be from the homolysis of DPDC and subsequent hydrogen abstraction during the rearomatisation stage.

## Chapter One

Scheme 26 Synthesis of quinoline derivative ${ }^{24}$
A similar class of reactions were used by Bowman in the synthesis of Camptothecin, ${ }^{76-80}$ mappicine, luotonin ${ }^{76}$ and Zanardi's synthesis of phenanthridine 98 (Scheme 27). ${ }^{77}$ The key step in these reactions was a 6 -endo attack of an aryl radical 96 onto the imine, to give the aminyl radical intermediate 97. This was followed by re-aromatisation to furnish phenanthridine $\mathbf{9 8}$ in $19 \%$ yield. The mechanism of re-aromatisation for this reaction involves extrusion of the tert-Bu group. ${ }^{77}$ Reactions involving re-aromatisation from extrusion of an alkyl group have been reviewed by Bowman et al. ${ }^{78-79}$

## Chapter One

## Scheme 27 Zanardi's synthesis of phenanthridine ${ }^{77}$

### 2.5 Aromatic radical cyclisation onto aromatics

Over the last decade, the synthesis of polyaromatics by cyclisation of aryl radicals onto aromatic rings has become popular. The synthesis of phenanthrene derivatives from cisstilbenes have recently been used in the synthesis of steganone. ${ }^{81}$ The aryl radical 99 generated from homolysis of the corresponding bromo aromatic compound with $\mathrm{Bu}_{3} \mathrm{SnH}$ (not shown) cyclised onto the second aromatic ring leading to intermediate $\mathbf{1 0 0}$. Rearomatisation presumably occurs by hydrogen abstraction of the cyclohexadienyl intermediate by the initiator (AIBN) as discussed previously, no evidence to the contrary has been presented by Harrowven et al. ${ }^{82}$ Phenanthrene 101 was furnished in $32 \%$, which showed that disproportionation may possibly be responsible for the oxidation process (Scheme 28). ${ }^{81}$

## Chapter One

## Scheme 28 Narasimhan synthesis of phenanthrene ${ }^{81}$

In addition to the above example, this methodology has been used to synthesise a range of polyaromatic natural products e.g. $\beta$-copaena, $\beta$-ylangene, lemnalol, ${ }^{83-84}$ seychellene, ${ }^{85}$ and towards the synthesis of vitamin $D_{3}{ }^{86}$ In a related reaction, Harrowven, ${ }^{82}$ used cis-stilbene (Scheme 29). In this case, the accepting aromatic ring was not electron rich but electron poor. Cis-4-cyano stilbene $\mathbf{1 0 2}$ was treated under classical radical conditions (tributyltin hydride, AIBN) to generate the aryl radical intermediate 103, which could add via an intramolecular exolendo-trig cyclisation to give the cyclohexadienyl radical intermediate 104. Re-aromatisation of the radical intermediate $\mathbf{1 0 5}$ probably occurs as described above, involving the initiator either homolysed or intact to give phenanthrene in $85 \%$ yield. Disproportionation can be ruled out as a mechanistic possibility. This reaction was repeated for the electron rich cis-3methoxy stilbene 106, under similar conditions to furnish regioisomers $\mathbf{1 0 7}$ and $\mathbf{1 0 8}$ in high yield ( $82 \%$ ). This should be compared to results from cis-3-cyano stilbene that gave similar regioisomers at slightly lower yields (78\%) (not shown).

## Chapter One

Scheme 29 Harrowven's synthesis of phenanthridines ${ }^{82}$
Harrowven ${ }^{87}$ has also shown that the cis stilbene 109 (Scheme 30) when treated with tributyltin hydride furnished the aryl radical intermediate 110. This radical then added onto to the aromatic ring to give the cyclohexadienyl radical intermediate $\mathbf{1 1 1}$. Re-aromatisation furnished the helicene $\mathbf{1 1 2}$ in $52 \%$ yield. Alternatively, the radical intermediate $\mathbf{1 1 0}$ can undergo addition onto C-7, leading through re-aromatisation to furnish dibenzo $[a, h]$ anthracene $\mathbf{1 1 3}$ in $17 \%$ yield. Preference for the C-5 over C-7 attack was evident. The reason for this selectivity is not clear, but is most likely to occur because of a more favourable SOMO-LUMO interaction with C-5. Possible rearomatisation mechanisms were not mentioned.

## Chapter One

## Scheme 30 Harrowven's synthesis of helicene- $\mathbf{1}^{87}$

An alternative approach by Harrowven ${ }^{88}$ to furnish [5]-helicene $\mathbf{1 1 2}$ is the use of (Z,Z)-1,4-bis-iodo stilbenes. Treatment of the bis-iodo substrate (not shown) under classical radical conditions (tributyltin hydride, AIBN) furnished the di-radical intermediate 114, which underwent radical coupling to furnish the [5]-helicene 112 in $35 \%$ yield and the by-product dibenzo[a,h]anthracene 113 in 27\% yield (Scheme 31). Since aryl radical formation is relatively fast compared to homolytic aromatic substitution it is indeed likely that a biaryl intermediate like $\mathbf{1 1 4}$ actually is formed, rather than the formation of one radical followed by the formation of another. There is however no evidence for radical-radical coupling, which is a fast process. In this reaction a fourfold excess of tributyltin hydride was used to push the reaction towards bicyclisation. Harrowven stated that the driving force for re-aromatisation overcame the energy barrier caused by the lack of planarity on helicene.

## Chapter One

Scheme 31 Harrowven's synthesis of helicene and phenanthrene ${ }^{88}$

### 2.6 Alkyl radical cyclisation onto heteroaromatics

Cyclisation of radicals into heteroaromatics is a relatively new process. The first example of this involves cyclisation of an alkyl radical into a protonated pyridinium salt. ${ }^{89}$ Intermolecular and intramolecular aromatic homolytic substitutions into heterocycles are relatively well researched. An example of an intermolecular addition into an heteroaromatic was first demonstrated by Minisci, ${ }^{90}$ whereby the nucleophilic alkyl radical ( $\mathbf{R} \cdot$ ) can add intermolecularly into the protonated pyridinium salt $\mathbf{1 1 5}$ to give the radical cationic species 116. Loss of a proton yields the radical $\alpha$ to the nitrogen atom 117. Re-aromatisation under oxidative conditions leads to the fully aromatic product 118 as depicted in Scheme 32.

Scheme 32 Murphy's reaction of protonated pyridinium salts

## Chapter One

An intramolecular version of this reaction was accomplished by Murphy. ${ }^{91-92}$ In this example (Scheme 33), treatment of the 2-iodoalkyl pyridinium salt $\mathbf{1 1 9}$ with tributyltin hydride ( 1.3 eq.) and AIBN (1.2 eq.) gave the nucleophilic alkyl radical $\mathbf{1 2 0}$ which could add into the pyridinium ring to furnish the tetrahydroquinolizinium salt $\mathbf{1 2 1}$ in $60 \%$ yield.

Scheme 33 Murphy's intramolecular addition into pyridinium salt

### 2.6.1 Radical cyclisation onto pyrazoles

Intramolecular cyclisation onto pyrazoles have been accomplished to give 4-phenyl pyrazole derivatives $\mathbf{1 2 5} .{ }^{93}$ Reaction of a 4-phenylpyrazole phenylselenyl precursor $\mathbf{1 2 2}$ with tributyltin hydride ( 1.3 eq.) and ACCN ( 1.5 eq .) gave the alkyl radical intermediate 123 (Scheme 34), which underwent a 6 -exo cyclisation to give the intermediate $\pi$-radical 124 followed by oxidation to furnish 4-phenylpyrazole 125 in $63 \%$ yield. For cyclisations involving a 5-exo or 7-exo cyclisation, there was a considerable amount of reduced product 126 formed. There was no product pertaining to the other regioisomer 127.

## Chapter One

$\mathrm{Z}=\mathrm{Ph}, \mathrm{n}=1 \mathbf{1 2 5 a}=38 \% ; \mathbf{1 2 6}=17 \% ; \mathrm{n}=2 \mathbf{1 2 5 b}=63 \% ; \mathbf{1 2 6}=0 \% ; \mathrm{n}=3 \mathbf{1 2 5} \mathrm{c}=37 \% ; \mathbf{1 2 6}=48 \%$

## Scheme 34 Intramolecular cyclisation of pyrazine ${ }^{93}$

The reaction was repeated using the ester ${ }^{93}$ [COOEt] on C-3 of the pyrazole (Scheme 35). Treatment of the radical precursor $\mathbf{1 2 8}$ with tris(trimethylsilyl)silane (1.3 eq.) and triethylborane $\left(\mathrm{Et}_{3} \mathrm{~B}\right)(1.5$ eq.) as the radical initiator in refluxing toluene under an aerial atmosphere furnished the alkyl radical $\mathbf{1 2 9}$ which underwent 6-exo cyclisation to furnish the cyclic radical intermediate $\mathbf{1 3 0}$ followed by oxidation to give the bicyclic product 131 in $36 \%$ yield. Both 5-exo and 7-exo cyclisations were disfavoured, and only the reduced product 132 was isolated, due to faster H -abstraction of hydrogen by the intermediate radical 129. In addition, none of the regioisomeric cyclised product 133 was observed, which indicated the regioselectivity was more favourable towards C-5 than C-2 (the nitrogen atom adjacent to the alkyl chain).

## Chapter One

$\mathrm{Z}=$ COOEt, $\mathrm{n}=1 \mathbf{1 3 1} \mathbf{a}=0 \% ; \mathbf{1 3 2}=73 \% ; \mathrm{n}=2 \mathbf{1 3 1 b}=36 \% ; \mathbf{1 3 2}=0 \% ; \mathrm{n}=3 \mathbf{1 3 1} \mathbf{c}=0 \% ; \mathbf{1 3 2}=62 \%$
Scheme 35 Reaction of pyrazole (ester) on radical cyclisation ${ }^{93}$
The mechanism for the oxidative step $\mathbf{1 3 0}$ to $\mathbf{1 3 1}$ is not clear, but it is reported that the stability of the $\pi$-radical intermediate $\mathbf{1 3 1}$ is crucial (to aromatisation). ${ }^{94-98}$ The rearomatisation could occur from H -abstraction by the ethyl radical formed during the oxygen-generated breakdown of $\mathrm{Et}_{3} \mathrm{~B}$ that was used as the initiator. With ACCN as initiator, more than one equivalent of initiator was required, which indicated that involvement of ACCN or its breakdown products (1-cyanocyclohex-1-yl radical) was involved in re-aromatisation. ${ }^{57,}$, 94-103

### 2.6.2 Radical cyclisation onto imidazoles

Further studies were conducted involving cyclisation onto imidazoles ${ }^{94}$ (Scheme 36). In these reactions the alkyl bromide radical precursor $\mathbf{1 3 4}$ when treated with tributyltin hydride ( 1.5 eq.) and AIBN ( 0.25 eq.) generated the nucleophilic alkyl radical intermediate 135, which underwent cyclisation at the electrophilic C-2 position of the imidazole, leading to the $\pi$-radical intermediate $\mathbf{1 3 6}$ followed by oxidation to the product 137. Again, it was observed that 6 -exo cyclisation was more selective (no reduced product) than that concerning the 5-exo and 7-exo cyclisation (both generating the

## Chapter One

reduced product $\mathbf{1 3 8}$ ). There was no regioisomer 139 resulting from cyclisation onto the C-5 position.

Key: a) $\mathrm{n}=1, \mathbf{1 3 7}=42 \% ; \mathbf{1 3 8}=10 \%$ b) $\mathrm{n}=2, \mathbf{1 3 7}=49 \% ; \mathbf{1 3 8}=0 \%$ c) $\mathrm{n}=3, \mathbf{1 3 7}=14 \% ; \mathbf{1 3 8}=8 \%$.

## Scheme 36 Intramolecular cyclisation of imidazole ${ }^{94}$

In order to explore the regioselectivity of this reaction, the reaction was repeated, blocking the C-5 of the imidazole with a methyl group 140 (Scheme 37). The result was complete selectivity towards C-2 cyclisation leading to the bicyclic product $\mathbf{1 4 1}$ in $75 \%$ yield. Furthermore, regioselectivity was investigated, whereby C-2 of the imidazole was blocked with a methyl group $\mathbf{1 4 2}$. This resulted in only reduced product $\mathbf{1 4 3}$ being isolated in $46 \%$ yield. The regioselectivity would appear to be determined by nucleophilic alkyl radical addition onto the electrophilic $\beta$-position of the imidazole. This reaction was also investigated with tributylgeranium hydride. ${ }^{104}$

Scheme 37 Blocking of the C-2 and C-5 with methyl group ${ }^{94}$

## Chapter One

In addition, a carbaldehyde in the $\alpha$-position of the imidazole $\mathbf{1 4 4}$ gave good yields of the 6 -membered ring product $\mathbf{1 4 5}$ in $53 \%$ yield (Scheme 38). However, attempts to mediate 5-exo cyclisation from the radical precursor 146 failed leading to the reduced product 147.

## Scheme 38 Intramolecular cyclisation of pyrrole and imidazole ${ }^{99}$

In this paper, there is no specific proposed mechanism to explain the oxidative radical cyclisation of these substrates with $\mathrm{Bu}_{3} \mathrm{SnH}$. There are three putative mechanisms proposed in the earlier papers: (1) formation of a dihydro product and subsequent air oxidation to achieve re-aromatisation. However this is unlikely since reactions are performed under an inert atmosphere; (2) H-abstraction by AIBN and/or 2-cyanoprop-2yl radicals; ${ }^{105}$ although Lobo, Prabhaker et.al, ${ }^{106}$ conducted experimental work on similar oxidative cyclisation, which showed that the hydrogen that is lost, is not abstracted by 2 -cyanoprop-2-yl radicals. (3) a pseudo- $\mathrm{S}_{\mathrm{RN}}{ }^{1}$ mechanism. ${ }^{94}$

### 2.7 Ipso-substitution and extrusion of a good radical leaving groups

The reaction of radical precursor 148 (Scheme 39) ${ }^{107}$ when treated with tributyltin hydride and AIBN led to the alkyl radical intermediate 149. The intermediate radical is weakly nucleophilic and adds to the electrophilic C-2 carbon leading to the $\pi$-radical intermediate 150. Elimination of the leaving group furnished the product 151. In the previous section cyclisation occurred at sites substituted by an H -atom and not at sites blocked by substituents (e.g. COOEt). However, if the substituent (e.g. Z, 148) is a good

## Chapter One

radical leaving group, ipso substitution with loss of this group can occur. Caddick has used this methodology to furnish [1,2-a] indoles using sulfone, sulfide and sulfoxide groups as leaving groups in substituted indoles. ${ }^{108}$ Highest yields were obtained from 6exo attack onto sulfoxides (tosyl group).

$\mathrm{Z}=\mathrm{Ts}, \mathrm{n}=1 ; \mathbf{1 5 1} \mathbf{a}=52 \%, \mathrm{n}=2 ; \mathbf{1 5 1 b}=48 \%, \mathrm{n}=3 ; \mathbf{1 5 1} \mathbf{c}=63 \%, \mathrm{Z}=\mathrm{PhSO}_{2}, \mathrm{n}=1 ; \mathbf{1 5 1} \mathbf{a}=51 \%, \mathrm{Z}=$ $\mathrm{PhS}, \mathrm{n}=1 ; \mathbf{1 5 1} \mathbf{a}=16 \%$.

## Scheme 39 Intramolecular ipso cyclisation of imidazoles ${ }^{107}$

There was no noticeable change in yield for $\mathrm{n}=1$ on varying the tosyl leaving group 151a in $52 \%$ yield and the phenylsulfonyl leaving group 151a in $51 \%$ yield. The low yield for the phenylsulfanyl group 151a (16\%) is attributed to this leaving group not being sufficiently electron withdrawing to facilitate complete attack at C-2 by the weakly nucleophilic alkyl radical. The same approach can be used to prepare [1,2- $\alpha$ ]fused benzimidazole $\mathbf{1 5 2}$ as depicted in Scheme 40. ${ }^{108-110}$ The radical precursor $\mathbf{1 5 2}$ was treated with tributyltin hydride and AIBN to give the alkyl radical intermediate $\mathbf{1 5 3}$. This underwent an attack on the electrophilic C-2 carbon of the benzimidazole to give the $\pi$-radical intermediate $\mathbf{1 5 4}$, and elimination of the phenylsulfanyl group to give the product 155.

## Chapter One

## Scheme 40 Intramolecular ipso cyclisation of benzimidazole ${ }^{110}$

The 5-exo cyclisation to $\mathbf{1 5 5}(\mathrm{n}=1)$ proceeded in a higher yield to that of the analogous imidazole reaction in $16 \%$ yield as depicted in Scheme 39. The yields for the benzimidazole were reasonably good, with the 6-exo cyclisation providing higher yields (54\%) than the 5-and 7-exo cyclisations. This was explained because the imidazole ring in benzimidazole has less aromatic character than in imidazole, and that addition of the alkyl radical was more facile, and also because the weakly electron withdrawing (phenylsulfanyl) group facilitates cyclisation over reduction.

### 2.8 Cyclisation of pyrroles

Related work by Bowman ${ }^{94}$ on pyrroles has shown similar selectivities with respect to the 6-exo cyclisation (no reduced product observed). In this case the bromo alkyl radical precursor 156 was treated with tributyltin hydride (1.5 eq.) and AIBN ( $0.25 \%$ ), which generated the alkyl radical intermediate 157 followed by addition onto the electrophilic C -2 to yield the $\pi$-radical intermediate 158, which after oxidation furnished the product 159 as depicted in Scheme 41. Again, both the 5-exo and 7-exo cyclisations were accompanied by small amounts of reduced products $\mathbf{1 6 0}$.

## Chapter One

Key: a) $\mathrm{n}=1, \mathbf{1 5 9}=46 \% ; \mathbf{1 6 0}=11 \% ;$ b) $\mathrm{n}=2, \mathbf{1 5 9}=45 \% ; \mathbf{1 6 0}=0 \% ;$ c) $\mathrm{n}=3, \mathbf{1 5 9}=54 \% ; \mathbf{1 6 0}=18 \%$.

## Scheme 41 Intramolecular cyclisation of pyrrole-2 ${ }^{94}$

Several cyclisations onto the C-2 position of imidazoles proceed by reductive cyclisation and not aromatic homolytic substitution ${ }^{48}$ that indicates that reduction of the intermediate radical by $\mathrm{Bu}_{3} \mathrm{SnH}$ is faster than re-aromatisation. However, when an electron-withdrawing group is present in the $\mathrm{C}-3$ position, normal aromatic homolytic substitution is largely favoured. ${ }^{111-116}$

### 2.9 Acyl radical cyclisation on pyrroles

Acyl radicals also undergo addition reactions. ${ }^{97}$ In this example, treatment of the phenylselenyl radical precursor 161 with tributyltin hydride and AIBN furnished the acyl radical intermediate 162 as illustrated in Scheme 42. This was followed by exo attack onto the pyrrole to give the $\pi$-radical intermediate 163 , followed by oxidation to the product 164a $(\mathrm{n}=1)$ in $31 \%$ yield and $\mathbf{1 6 4 b}(\mathrm{n}=2)$ in $20 \%$ yield. No reduced product 165 was isolated. An alternative product can be formed from the intermediate 166. Decarbonylation gave the alkyl radical 166 that could add in an exo-fashion onto the pyrrole to give the $\pi$-radical intermediate $\mathbf{1 6 7}$, followed by oxidation to the product 168a $(\mathrm{n}=1)$ in $0 \%$ yield and $\mathbf{1 6 8 b}(\mathrm{n}=2)$ in $13 \%$. Only the reduced product $169 \mathbf{a}(\mathrm{n}=$ 1) was isolated in $34 \%$ yield.

## Chapter One

Scheme 42 Intramolecular cyclisation of pyrroles using acyl radicals ${ }^{97}$ It should be noted that decarbonylation is an exothermic process. The rate of CO loss (approximately $2 \times 10^{2} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ ) at $80^{\circ} \mathrm{C}$ to generate a primary alkyl radical, is much slower than CO addition ( $6.3 \times 10^{5} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ ) at $80^{\circ} \mathrm{C}$ for primary alkyl radicals. ${ }^{117}$ In order to facilitate the synthesis of $\mathbf{1 6 4}$ this reaction was conducted under a CO atmosphere. Furthermore, this methodology has been applied towards tetracyclic heterocycles ${ }^{119}$ from 2-indolylacyl radicals. The mechanism for re-aromatisation ${ }^{98}$ in this reaction is still unclear. In the $\mathrm{Bu}_{3} \mathrm{SnH}$ mediated oxidative cyclisation, more than one equivalent of AIBN is required, which would suggest that AIBN is involved in an $\mathrm{H}-$ abstraction mechanism for this step (see Scheme 20).

Azo compounds can act as oxidants, and as such would give dihydro-AIBN 172 (Scheme 43) as the expected product. Subsequently, experimental studies using AIBMe 170 as the radical initiator with radical precursor 161b furnished the cyclised product

## Chapter One

164b and dihydro-AIBN 171 indicating that AIBMe 170 was responsible for the oxidative step.

## Scheme 43 Mechanism indicating AIBN involvement in re-aromatisation

### 2.10 Aryl radical cyclisation onto heteroaromatics

A popular approach to polyheteroaromatics ${ }^{119-120}$ is the addition of an aryl radical onto another heteroaromatic such as quinoline (Scheme 44). Radical intermediates 173a and $\mathbf{1 7 3 b}$ are produced from homolysis of the corresponding $\mathrm{C}-\mathrm{X}$ bonds with $\mathrm{Bu}_{3} \mathrm{SnH}$ (not shown). The use of iodo aromatics is superior in terms of yield to the bromo analogues. The stilbene radical intermediate 173a, underwent 6-exo/endo-trig cyclisation to furnish the two regioisomers resulting from attack at $\mathrm{C}-2, \mathbf{1 7 4 a}$ in $57 \%$ yield and $\mathrm{C}-4, \mathbf{1 7 5 a}$ in $38 \%$ yield. ${ }^{119}$ When the reaction was repeated without the alkene bridge (e.g. an ethyl bridge between the aromatic and the quinoline 173b), yields were slightly less for the C2 analogue $\mathbf{1 7 4 b}$ in $51 \%$ yield and C-4, 175b in $23 \%$ yield. The low yield from the bromo precursor was due to several intractable products. The use of the iodide precursor proved more effective. Again, it was shown that the product from C-4 addition occurred in higher yields. The mechanism for re-aromatisation was postulated to go through two mechanistic pathways as described by Harrowven et al. ${ }^{119}$ Similar methodology using cobalt (II)-salophen was used in the synthesis of Toddaquinoline. ${ }^{121}$

## Chapter One

Key: Bromo precursor $\mathrm{Bu}_{3} \mathrm{SnH}, 0.9$ eq. AIBN $\mathrm{PhMe}, 80^{\circ} \mathrm{C} ; \mathbf{1 7 4 7 a}=24 \%, \mathbf{1 7 5 a}=46 \% ; \mathbf{1 7 4 b}=18 \%$, $\mathbf{1 7 5} \mathbf{b}=15 \%$; Iodo precursor $\mathrm{Bu}_{3} \mathrm{SnH}, 0.1$ eq. $\mathrm{AIBN}, \mathrm{PhMe}, 80^{\circ} \mathrm{C} ; \mathbf{1 7 4} \mathbf{a}=38 \%, \mathbf{1 7 5 a}=57 \% ; \mathbf{1 7 4 b}=23 \%$, $\mathbf{1 7 5 b}=51 \%$.

## Scheme 44 Harrowven's synthesis of polyheteroaromatics ${ }^{119}$

Cyclisations onto indoles have been explored by Harrowven ${ }^{122}$ using halo $N$-benzyl indoles derivative 176. In this case the aryl radical 177 generated from tributyltin hydride mediated homolysis of the aryl iodide underwent a 5-exo trig cyclisation to furnish the radical intermediate 178. Hydrogen abstraction from another molecule of tributyltin hydride furnished the tetracycle $\mathbf{1 7 9}$ in $80 \%$ yield and the reduced product 180 in <5\% yields as depicted in Scheme 45.

## Scheme 45 Intramolecular cyclisation of indoles

## Chapter One

Further developments of this reaction were employed in the synthesis of several heterocycles namely-deoxyvascinone, mackinazoline, luotinin A, tryptanthrin. ${ }^{123}$

The Jones' group has developed cyclisation onto pyrroles further. ${ }^{124-126}$ An ortho bromo anilide derivative $\mathbf{1 8 1}$ when treated with tributyltin hydride ( 0.02 M ) and substoichiometric amount of AIBN furnished the aryl radical intermediate $\mathbf{1 8 2}$ as illustrated in Scheme 46. This could undergo three reactive pathways. The radical intermediate $\mathbf{1 8 2}$ could undergo 6-endo cyclisation via the radical intermediate 183 onto the pyrrole to furnish the product 186. It could undergo 6-exo cyclisation via the radical intermediate 184 onto the pyrrole to give the regioisomeric product 187. Finally, it could undergo 5exo cyclisation via the radical intermediate $\mathbf{1 8 5}$ to furnish the spirocyclised product 188.

It is important to note the effects of substituents on the nitrogen atom of the pyrrole ring in controlling the reaction. If unsubstituted groups $\left(\mathrm{R}^{2}=\mathrm{H}\right)$, then regioisomeric products 186a ( $R^{1}=\mathrm{Me}, \mathrm{R}^{2}=\mathrm{H}, 37 \%$ ) and 187a $\left(\mathrm{R}^{1}=\mathrm{Me}, \mathrm{R}^{2}=\mathrm{H}, 15 \%\right)$ dominated. Conversely, cyclisation using $N$-t-Boc group led predominately to the spirocyclised product $\mathbf{1 8 8 b}\left(\mathrm{R}^{1}\right.$ $\left.=\mathrm{Me}, \mathrm{R}^{2}=\mathrm{Boc}\right)$ in $31 \%$ yield, with the regioisomers as minor products $(\mathbf{1 8 6} \mathbf{b} / \mathbf{1 8 7} \mathbf{b}=$ $18 \% / 1 \%$ ). If an electron-withdrawing group was attached to the nitrogen atom of the pyrrole, only 186c ( $\mathrm{R}^{1}=$ SEM, $\mathrm{R}^{2}=\mathrm{Me}$ ) was furnished in $43 \%$ yield. The regioselectivity was unaffected when substitutents were on the aromatic ring. The reasons for the differences in the reactivity between the varying groups on the nitrogen atom of the pyrrole is not entirely clear nor is the mode of re-aromatisation given that sub-stoichiometric amounts of initiator are reported to have been used.

Key: $R^{1}=M e, R^{2}=H ; \mathbf{1 8 6} \mathbf{a}=37 \%, \mathbf{1 8 7} \mathbf{a}=15 \% ; R^{1}=M e, R^{2}=B o c ; \mathbf{1 8 6} b=18 \%, \mathbf{1 8 7} \mathbf{b}=1 \%, \mathbf{1 8 8 b}=$ $31 \% ; \mathrm{R}^{1}=\mathrm{SEM}, \mathrm{R}^{2}=\mathrm{Me} ; \mathbf{1 8 6} \mathbf{c}=43 \%$

## Scheme 46 Intramolecular cyclisation onto pyrroles ${ }^{125}$

### 2.11 Trapping of the cyclohexadienyl radical intermediate

Recent developments in radical chemistry have led to many possible routes to form spirocyclised natural products through in-situ trapping of the cyclohexadienyl radical intermediate. Zard's method has shown that spirolactams ${ }^{127}$ can be prepared from N benzyl trichloroacetamides using nickel powder/acetic acid. Furthermore, Jones' has used this methodology towards the spirooxindole natural products-horsfiline, (Scheme 47) elacomine, alstonisine and spirotryprostatin $A .{ }^{128}$

## Chapter One

Scheme 47 An example of spirocyclisation ${ }^{128}$
Spirodienones have been synthesised via intermolecular ipso substitution from N -methoxy-(4)-(halogeneophenyl) amides and hydroxyl (tosyloxy) iodobenzene (HTIB)/trifluoroethanol (TFEA). This methodology was developed for the synthesis of 1-azaspiro-[4,5]-decane-mediated natural products-TAN1251A-D, FR901483I, lepadiformine and cylindricine A-F. ${ }^{129}$ Furthermore, this methodology has been used by Curran and de Turiso in the synthesis of spirocyclohexadienone intermediates, which could be applied to synthesis of SR121463A and aza-galanthamine. ${ }^{130}$

### 2.12 Spirocyclisation followed by rearrangement reactions

In cases where there is a good radical leaving group $\alpha$ to the intermediate cyclohexadienyl radical, it can undergo re-aromatisation with extrusion of the radical leaving group; this can result in rearrangement as shown in this example Scheme 48.

Azacoumarins $\mathbf{1 9 4}^{131}$ have been prepared by a unique double ipso substitution from aryl benzoate 189. The reaction goes via an initial 1,5-ipso attack at the 2-position of the pyridine 190 to generate the spirocyclised intermediate 191 followed by re-aromatisation and fragmentation of the carbon-oxygen bond to furnish the carbonyloxy radical intermediate 192. The aromatic carbonyloxy radical ( $\mathrm{k}=10^{4}-10^{5} \mathrm{~s}^{-1}$ ) is considerably slower than alkyl carbonyloxy radical $\left(\mathrm{k}=10^{8}-10^{10} \mathrm{~s}^{-1}\right)$, and allows the radical intermediate 192 time to undergo a second 1,6-ipso attack at the methoxy position

## Chapter One

leading to the aryl radical intermediate 193. This is followed by extrusion of the methoxy group to furnish the azacoumarin 194. It should be noted that the use of the methoxy group was crucial to the whole rearrangement process.

Scheme 48 Complex double ipso cyclisation to form azacoumarins ${ }^{131}$

### 3.0 Aryl migration

Aryl groups can undergo migration reactions ${ }^{132-134}$ generally via the intermediacy of a spirocyclohexadienyl system followed by re-aromatisation and cleavage of the appropriate bonds. Wieland ${ }^{135}$ first reported radical aryl migration reactions in 1911. There has been an extensive investigation of 1,2-ipso aryl migrations, however, there are currently no literature reports concerning 1,3-aryl migrations, though numerous examples regarding 1,4-aryl migrations have been reported. The most frequent type of aryl migrations are 1,5 -migrations. In the example illustrated in Scheme 49, ${ }^{136}$ tributyltin-mediated radical abstraction of the iodo group in 195 generated the aryl

## Chapter One

radical intermediate 196, which underwent an initial 5-exo-trig cyclisation resulting in the spirocyclic intermediate 197. Re-aromatisation and fragmentation gave the radical intermediate 198. There were three possible pathways observed that can occur in this system. The radical intermediate $\mathbf{1 9 8}$ can (A), undergo hydrogen atom abstraction from tributyltin hydride to give the methyl ether 199 (6\%); (B) undergo the slower 6-endolexo-trig cyclisation leading to the benzo[c]chromene radical intermediate 200 followed by re-aromatisation to the product 201 (27\%); or (C) via a fragmentation process leading to the phenol 202 (46\%). This last step was not rationalised by Harrowven and is currently under further investigation.

Scheme 49 Harrowven's intramolecular cyclisation of an aryl ether ${ }^{136}$

## Chapter One

Harrowven ${ }^{136}$ synthesised the natural product isoauparin 203 through the same methodology as described above (Figure 1).

203
Figure 1 Structure of isoaucuparin

Under similar conditions, tributyltin hydride-mediated radical abstraction of the ortho halo-compound 204 furnished the aryl radical 205 which underwent a 1-5-ipso attack to give the spirocyclised radical intermediate 206 as depicted in Scheme 50. Rearomatisation to give $\mathbf{2 0 7}$ followed by possible hydrogen abstraction from another molecule of tributyltin hydride resulted in the biaryl 208 via an aryl migration. ${ }^{98}$ Alternatively, the radical intermediate 206 underwent a neophyl rearrangement to give the $\sigma$-complex 209 which upon oxidation (re-aromatisation) led to the benzo[c]chromane $210(\mathrm{Me}=36 \%, \mathrm{OMe}=21 \%)$. In this reaction, the cyclisation via the neophyl rearrangement was faster than the ipso substitution followed by fragmentation.

## Chapter One

Synthesis of biaryls can be achieved by nitrogen to carbon aryl migration. For example, N -methanesulfonamide 211 is converted to the $N$-(3-arylpropyl) amide 214. ${ }^{139}$ Formation of radical 212 by homolysis of the corresponding $\mathrm{C}-\mathrm{Br}$ bond using tributyltin hydride and AIBN led to a 1,5-ipso attack to furnish the spirocyclohexadienyl radical intermediate 213, re-aromatisation followed by homolytic cleavage of the $\mathrm{C}-\mathrm{N}$ bond furnished the sulfonamide 214 in $\mathbf{7 2 \%}$ yield as depicted in Scheme 51. The reaction proceeds through a captodatively-stabilised spirocyclised radical intermediate 213. It is noted that varying the type of substituent on the nitrogen atom, affects the outcome for the rearranged product, as such, methanesulfonamide is more efficient (in furnishing the rearranged product) than the methyl ester or $p$-toluenesulfonyl group. The same authors used this approach for oxygen to carbon aryl migrations. ${ }^{138}$

Scheme 51 Nitrogen to carbon aryl migration ${ }^{137}$
It is rarer but also possible to get migrations occurring in a $1,4{ }^{-139-140}$ and 1,6 fashion. ${ }^{141}$ For example, treatment of the xanthate $\mathbf{2 1 5}$ with dilauroyl peroxide gave the radical intermediate 216 which could then undergo a 1,4-ipso ${ }^{139}$ cyclisation leading to a spiroazetidinone radical intermediate 217 as illustrated in Scheme 52. This was followed by re-aromatisation and cleavage of the carbon-nitrogen bond, which gives an amidyl radical intermediate 218. This can then abstract a hydrogen atom presumably from the

## Chapter One

solvent to furnish the rearranged product $\mathbf{2 1 9}$ in $71 \%$ yield. Radical 216 was hindered from cyclisation onto the aromatic ring, due to steric effects when $\mathrm{R}=$ tert-butyl. However if the nitrogen substituent is changed from the tert-butyl group to a methyl group, then only the cyclised product $\mathbf{2 2 0}$ is observed in $\mathbf{3 9 \%}$ yield.

## Scheme 52 Smiles rearrangement

An example of 1,6-migration is illustrated in Scheme 53. Tributyltin hydride-mediated radical formation from the bromo compound $\mathbf{2 2 1}$ generated the aryl radical 222, which underwent an 1,6 -ipso attack onto one of the three phenyl rings attached to the silyl group to give the spirocyclohexadienyl radical intermediate $\mathbf{2 2 3} .^{142-143} \mathrm{Re}$-aromatisation followed by homolytic cleavage of the carbon-silicon bond led to the silyl radical intermediate 224. Extrusion of the silyl group furnished the biaryl alcohol $\mathbf{2 2 5}$ in $71 \%$ yield. Phenyl migration from other groups was investigated. When the trimethyltin ( $\mathrm{Me}_{3} \mathrm{Sn}$-) substrate was used, it did not form the expected rearranged product, but instead the aryl radical intermediate $\mathbf{2 2 6}$ underwent a $\mathrm{S}_{\mathrm{H}} 1$ type of reaction to furnish the bicyclic silylated product 227. Ring opening of the cyclic silyl ether with methyllithium

## Chapter One

furnished the silylated benzyl alcohol 228 in $84 \%$ yield. The use of a phenyl or methyl group gave exclusively the rearranged product.

## Scheme 53 Silicon to carbon aryl migration ${ }^{142}$

Struder has extensively investigated aryl migrations of sulfur to carbon. ${ }^{132-133}$ The thianeophyl type 1,2-phenyl migration from sulfur to carbon is known ${ }^{144}$ however, there is no radical 1,3-aryl migration of sulfur to carbon to date. The majority of sulfur to carbon reactions involve 1,4-, 1,5- and 1,6 aryl migration. In the following example, Studer et al. ${ }^{133}$ investigated radical 1,5 -aryl migration from sulfur in sulfonates to secondary Cradicals for stereoselective bond formations (Scheme 54). Starting from the iodide 229, tributyltin hydride and AIBN generated the secondary alkyl radical 230 that could undergo a 1,5-ipso attack into the phenyl ring to form the cyclohexadienyl radical intermediate 231. Re-aromatisation from $\beta$-elimination gave the alkoxysulfonyl radical intermediate 232. Extrusion of $\mathrm{SO}_{2}$ furnished the alkoxy radical 233 followed by H -

## Chapter One

abstraction to yield the product 234 in good yield (76\%) and high selectivity ( $d r=13: 1$ ) for the unsubstituted aryl group.

## Scheme 54 1.6-ipso aryl migration ${ }^{134}$

### 3.1. Radical cyclisation and rearrangement reactions of aryl sulfonamides

The further reactions and discussions in this thesis focus on the reactions of sulfonamides thus the following section comprises aromatic homolytic substitution and rearrangement reactions of aryl sulfonamides.

### 3.2 Alkyl radical cyclisation and rearrangements from aryl sulfonamides

Speckamp and Köhler ${ }^{145}$ reported that sulfonamide 235 (Scheme 55) when suitably substituted, could undergo a radical cyclisation reaction to give 236, if treated with azobisisobutyronitrile (AIBN) and tributyltin hydride (TBTH). However in addition to the cyclised products 236a-d, f, the rearranged products ${ }^{146}$ 237a-f and reduced products 238a-f were also detected.

## Chapter One

a) $\mathrm{X}=\mathrm{CH}_{3}, \mathrm{Y}=\mathrm{H} ;$ b) $\mathrm{X}=\mathrm{H}, \mathrm{Y}=\mathrm{H} ;$ c) $\mathrm{X}=\mathrm{OCH}_{3}, \mathrm{Y}=\mathrm{H} ;$ d) $\mathrm{X}=\mathrm{Cl}, \mathrm{Y}=\mathrm{H} ;$ e) $\mathrm{X}=\mathrm{CH}_{3}, \mathrm{Y}=\mathrm{CH}_{3} ;$ f) X $=\mathrm{NO}_{2}, \mathrm{Y}=\mathrm{H}$.

## Scheme 55 Speckamp sulfonamide reactions ${ }^{145}$

The effect of substituents 235a-f on the rate of reaction and ratios of all three products was determined. While cyclised products 236a-d,f arise via cyclisation into the aromatic nucleus (see Section 2.5) the rearranged product 237a-f were obtained by the attack of the initial alkyl radical 239 (Scheme 50) into the aryl ring in an ipso 1,5 fashion, resulting in a spirocyclised intermediate 240. Re-aromatisation and cleavage of the $\mathrm{C}-\mathrm{S}$ bond furnishes the sulfur centred radical 241 that upon elimination of $\mathrm{SO}_{2}$ furnished the observed product via the aminyl radical 242. The cyclised product 236 (Scheme 55) was formed from a 1,6 addition onto the aryl ring, while the reduced product 238a-f occurs via reduction by TBTH of $\mathbf{2 3 9}$ prior to cyclisation.

241

Scheme 56 Mechanism for rearranged amine 237
When the tosyl substrate 235a was dissolved in anisole at $22^{\circ} \mathrm{C}$ for 24 hrs , the cyclised product 236a predominated ( $68 \%$ ). Conversely, with diphenylether as the solvent $\left(190{ }^{\circ} \mathrm{C} / 30 \mathrm{~min}\right)$ the rearranged product 237a predominated (64\%). This showed that increasing the temperature alters the product distribution. Of course, if the ortho aryl positions were blocked, as with the mesitylene derivative 236e, only the rearranged product $\mathbf{2 3 7}$ e was isolated. Further studies investigated the effects of changing the initiating halogen on the product outcome. ${ }^{147}$ While the iodo-nitro derivative $\mathbf{2 3 5 f}$ as depicted in Scheme $\mathbf{5 7}$ gave the rearranged product $\mathbf{2 3 7 f}$ in $\mathbf{5 6 \%}$ yield.

## Chapter One

Scheme 57 Rearranged amide from nitro compound ${ }^{147}$
The corresponding bromide $\mathbf{2 4 3}$ furnished only the dimeric azo sulfonamide $\mathbf{2 4 4}$ in $51 \%$ yield (Scheme 58). This indicated that azo formation was faster than the $\mathrm{C}-\mathrm{Br}$ homolysis. Therefore, only iodides were used in further investigations.

## Scheme 58 Dimerisation from nitro compound

In order to broaden the scope of their reaction, Speckamp and Köhler investigated further changes to the aryl substituent. Heteroaryl sulfonamides were also tolerated, thus a pyridyl sulfonamide 245, (Scheme 49) gave the expected rearranged product 246 in $30 \%$ yield, and the reduced product 247 in $28 \%$ yield, but no cyclised product was observed.

Scheme 59 Synthesis of rearranged amine from pyridyl sulfonamide

## Chapter One

When a 1-naphthyl sulfonamide 248, (Scheme 60) was treated under the standard conditions described above, a novel dihydronaphthalene cyclised product $\mathbf{2 5 0}$ was formed in $81 \%$ yield instead of rearrangement or oxidative cyclisation. The explanation given was that the "orbital interaction between the allylic radical $\mathbf{2 4 9}$ and the extended further $\pi$-system is favourable". ${ }^{147}$

## Scheme 60 Cyclisation of 1-naphthyl sulfonamide

However, when the 2-naphthyl sulfonamide 251 (Scheme 61) was used, it led to the cyclised product 252 in $28 \%$ yield and the reduced product 253 in $14 \%$ yield, with no dihydronaphthalene derivative being isolated.

## Scheme 61 Cyclisation from 2 substituted naphthalene

### 3.3 Aryl radical cyclisation and rearrangement of aryl sulfonamides

While Speckamp investigated the addition of alkyl radicals onto aryl sulfonamides, Motherwell has investigated aryl radical additions onto similar substrates. The two main reaction modes (cyclisation and rearrangement) were also observed. This reaction has been used as a new method of Ar-Ar coupling ${ }^{148}$ (Scheme 62). This has been achieved

## Chapter One

by reacting biaryl sulfonamides $\mathbf{2 5 4 a} \mathbf{- b}$ with AIBN and tributyltin hydride. When substituents are on the ortho position of the sulfonamide $255 \mathrm{a}\left(\mathrm{R}^{1}=\mathrm{Me}, \mathrm{R}^{2}=\mathrm{H}\right)$, they undergo a 1,5 addition onto the second aryl ring which leads to the rearranged product 256a via the analogous pathway described earlier in Scheme 56. When the substitutents are in the para position of the sulfonamide $\mathbf{2 5 4 b}$ they undergo a 1,6- addition leading to a 1:1 ratio of cyclised $\mathbf{2 5 5 b}$ and rearranged product $\mathbf{2 5 6} \mathbf{b}$.

a) $\mathrm{R}^{1}=\mathrm{CH}_{3}, \mathrm{R}^{2}=\mathrm{H} ;$ b) $\mathrm{R}^{1}=\mathrm{H}, \mathrm{R}^{2}=\mathrm{CH}_{3}$

## Scheme 62 Motherwell's synthesis of biaryls and cyclic sulfonamides

Similarly, to the Speckamp studies varying the type of substitutents on the ortho and meta position of the aryl sulfonamide was investigated. ${ }^{149}$ Inclusion of a methylene group between the aryl ring and the sulfonyl group 257 led predominately to cyclised products 258 with no rearranged products detected by the 1,6 ipso mode. A number of heteroaromatic sulfonamides were tested (Scheme 64) ${ }^{150}$ including thiophenes 259 and quinolines 261 to furnish the cyclic sulfonamides 260 and 262 respectively.

## Chapter One

## Scheme 63 Examples of 1,7-ipso cyclisation reactions ${ }^{150}$

Inserting a further carbon between the aryl groups (but incorporating an alkene, i.e. unsymmetrical stilbenes) led to loss of $\mathrm{SO}_{2}$ but via a different mechanism to that previously discussed. ${ }^{151}$ Reaction of phenyl allyl sulfonamides 263 (Scheme 64) under standard radical conditions (AIBN, TBTH) led to an intermediate 264 via a 5-exo radical cyclisation onto the alkene. Elimination of sulfur dioxide subsequently yielded the rearranged product 265.

## Scheme 64 Motherwell's stilbene synthesis

### 3.4 Related work

Speckamp has previously shown that the use of alkyl iodides was essential for cyclisation/rearrangement with the use of bromides leading to alternative reactions i.e. azo formation in the case of $p$-nitroaryl substrates 243 (see Scheme 58). In related work,

## Chapter One

bromoaryl)-benzenesulfonamides ${ }^{152} \mathbf{2 6 6}$ (Scheme 65) if treated with $\left(\mathrm{Ph}_{2} \mathrm{HSi}\right)_{2}$ instead of TBTH could successfully be used to make the spirocyclised intermediate 267 which went on to yield rearranged biaryl products 268 in $61 \%$ yield, following rearomatisation,

## Scheme 65 Togo's synthesis of biaryls

Similarly, when sulfonamide xanthate 269 (Scheme 66) are treated with dilauroyl peroxide (DLP), the ensuring alkyl radical 270 can undergo a 1,5-ipso addition to give the spirocyclohexadienyl radical intermediate 271. Re-aromatisation led to the amidosulfonyl radical 272 which upon extrusion of sulfur dioxide furnished the amidyl radical 273 which gets reduced by 2-propanol to the rearranged amide product 274 in $81 \%$ yield. ${ }^{153}$

## Chapter One

### 3.5 Clark's work

While the majority of this previous work has involved the use of toxic $\mathrm{Bu}_{3} \mathrm{SnH}$, work by Clark ${ }^{154}$ has investigated whether similar reactions can be mediated by copper (I) complexes. ${ }^{155}$ It was found that the tosyl amide 275 when treated with $\mathrm{Cu}(\mathrm{I}) \mathrm{Cl}$ and an amine ligand led to a 1,5 addition into the aromatic ring forming an initial spirocompound 276, After re-aromatisation and loss of sulfur dioxide a novel rearranged product 277 was formed in $30 \%$ yield as illustrated in Scheme 67. No 6-endo cyclisation of 275 was observed.

Scheme 67 Clark's synthesis of rearranged amides
Thus, the use of $\mathrm{Bu}_{3} \mathrm{SnH}$ is not essential to mediate these types of reactions. The tremendous advantage of copper reagents is that the salts are inexpensive, and have a long shelf life. They are also non-toxic and the workup at the end of the reaction is easy to accomplish since purification consists of filtration using a small silica plug, and flushing the compound with ethyl acetate. In contrast, the disadvantages of the tin reagents are well known (eg toxicity, expense, the great difficulties encountered during purification and workup) but they tend to lead to reduced products as well in these types of reactions. This lowers the yield of the desired cyclised or rearranged product. The copper salts do not suffer from this disadvantage.

## CHAPTER TWO

## RADICAL REACTIONS OF $\boldsymbol{N}$-BUTYL-

(SUBSTITUTED)-ARYL SULFONAMIDES

## Chapter Two

### 1.0 Introduction

In light of the previous work discussed in Scheme 67, where substrate $\mathbf{2 7 5}^{154}$ was observed to undergo rearrangement to form the rearranged amide 277 under ATRC conditions (see Scheme 68). It was decided to investigate this type of reaction further. The product 277 was tentatively assigned from the crude NMR spectra, and was not isolated pure, in addition, according to Wongtap, ${ }^{156}$ the product 277 was contaminated with an uncharacterized product, tentatively assigned as the reduced product (10:90), nor was an alternative synthesis to authenticate this product proposed. The mechanism hypothesized for the rearranged amide was plausible, according to Speckamp's work. As has been previously shown that it is possible to mediate conventional atom transfer radical cyclisation (ATRC) ${ }^{157-160}$ reaction of unactivated bromides using copper bromide/TPA ${ }^{161-162} \mathbf{2 7 9}$.

## Scheme 68 Clark's synthesis of rearranged amides

The Clark group explored the rearrangement of unactivated bromide $\mathrm{R}=\mathrm{H} 278$ to amide 281. ${ }^{163}$ In order not to complicate the analysis of these reactions due to competitive cyclisation, the nitrogen group was changed from alkenyl 275 to N -butyl 278 as depicted in Scheme 69.

### 1.1 Aims and Objectives

The initial aim of this thesis was to determine the scope and limitation of this latter reaction (Scheme 69) by investigating the effects of the aryl substituent $(\mathbf{R})$ on the efficiency of this rearrangement. Later chapters will investigate the effects of N substitution and the acyl group. During this work, the effects of temperature and solvent will be investigated to determine whether this can influence the efficiency of the rearrangement. In addition, it was anticipated that it might be possible to obtain cyclised products by 6-exo cyclisation, into the aromatic ring and this was to be investigated.

### 2.0 Synthesis and use of sulfonamide starting materials

In order to develop a synthesis towards compounds 278, a preparation of the $N$-butyl substituted arylsulfonamides $\mathbf{2 8 3}$ was required. An initial synthesis of these classes of compounds is shown below (Scheme 70). A range of commercially available arylsulfonyl chlorides 281a-m as illustrated in Table 1 were carefully selected for this study, as it was necessary to have an array of electron withdrawing and electron donating substituents for kinetic studies.

## Chapter Two

## Scheme 70 Synthesis of starting sulfonamides

The Clark (Fullaway) group ${ }^{163}$ had previously developed a process towards substrate 278e, thus arylsulfonyl chlorides 281a, e-f (1.0 eq.) were treated with $n$-butylamine 282 ( 1.0 eq., $\mathrm{pKa} \approx 11$ ) ${ }^{164}$ and triethylamine (TEA) in dichloromethane (DCM), followed by acidic work-up to furnish the arylsulfonamides 283a-l. A similar method developed by Miyaka's ${ }^{165}$ involved equimolar amounts of the arylsulfonyl chloride 281, $n$-butylamine 282 and triethylamine Method A followed by aqueous work-up that was successful in the majority of cases. An alternative approach utilised $n$ butylamine 282 (3.0 eq.) alone in diethyl ether Method B. Arylsulfonamides 283a-l were purified either by recrystallization ${ }^{166}$ (using diethyl ether/hexane), or by flash chromatography. ${ }^{167}$ Method B gave higher yields for most substrates, as little purification was required. Purification of $\mathbf{2 8 3 g}$ using flash chromatography (petrol ether/ethyl acetate 6:1) furnished low yield (26\%). In addition, purification of the 2cyano substrate $\mathbf{2 8 3} \mathbf{m}$ using column chromatography failed. In light of these results, either Fullaway's method or Method B furnished excellent yields of arylsulfonamides 283.

Table 1 Synthesis of $N$-butyl-arylsulfonamides 283a-m.

### 2.1 Synthesis and use of the radical precursor 278

With a range of sulfonamides 283a-l in hand, the next goal was to react these with the appropriate acid bromide 284, to prepare a range of radical precursors 278a-l suitable for investigation (Scheme 71).

## Chapter Two

## Scheme 71 Synthesis of radical precursors 278

The primary method involved reacting sulfonamides $\mathbf{2 8 1 b} \mathbf{- c}, \mathbf{j}$ with 2 equivalents of $1.6 \mathrm{M} n$-butyllithium $(\mathrm{pKa} \approx 48)$ in anhydrous THF, followed by addition of the acid bromide 284. Unfortunately, upon scrutiny, this approach gave numerous unidentifiable products that could have been due to the concentration of $n$ butyllithium and consequently an improved procedure was required. Fullaway ${ }^{163}$ devised a good method toward the radical precursors $\mathbf{2 7 8}$ using equimolar quantities of 1.6 M butyllithium, the acid bromide 284 and starting sulfonamide 283 . The highest yield was for the $p$-tosyl compound 278e in $79 \%$ yield, followed by the phenyl compound 278a in $48 \%$ yield. However, there was negligible yield obtained for the mestylene compound $\mathbf{2 7 8 f}(7 \%)$, which could be attributed to steric effects from the two ortho methyl groups. The reaction conditions were modified (according to Fullaway's method) so that only 1 equivalent of $1.6 \mathrm{M} n$-butyllithium ( 1.0 eq .) Method A was used in the reactions. This significantly enhanced the reaction yields though considerable quantities of the eliminated acrylamides ${ }^{178}$ 286a-I (see Figure 2) were isolated (tentatively assigned by NMR). However, good yields for the 4-bromo derivative 278c in 70\% yield, 4-trifluoromethyl derivative 278k in 70\% yield and 4CN derivative $\mathbf{2 7 8 i}$ in $56 \%$ yield were achieved. To confirm the identify of 286a-l, the parent 286a was prepared unambiguously as below and its NMR spectra was compared to that obtained using Method A (Scheme 72).

## Chapter Two

## Scheme 72 Synthesis of eliminated product 286a

Due to the formation of unwanted elimination product 286a, an alternative method was used for the majority of the rest of the precursors. This involved changing from $n$-buytllithium to triethylamine ( 2.0 eq., $\mathrm{pKa} \approx 11$ ) Method $\mathbf{B}$ as a base. For the majority of reactions, this procedure produced poor (<32\%) 278e-g,j to fair (<58\%) $\mathbf{2 7 8} \mathbf{a}-\mathbf{b}, \mathbf{d}, \mathbf{h}$ yields of the desired products. In the case of the 4 -nitro derivative 278j even with one equivalent of triethylamine, a small amount of the eliminated acrylamide 286j was detected. In order to resolve this problem, a hindered base ( $\mathrm{N}, \mathrm{N}$-diisopropylethylamine, Hünig's base, 1.3 eq.) Method C was used to hinder competing E2 elimination. Although no elimination occurred, the reaction was significantly impeded, so that unreacted 284 was hydrolysed to the corresponding acid upon work-up. However, in the case of 3,5-trifluoromethyl derivative 2781 this approach was successful. All products were purified by flash chromatography to give sufficiently pure products that could be used for further studies (see Table 2).

## Chapter Two

### 3.0 Synthesis of the amine ligand-TPA 279

One of the most important reagents involved in these radical reactions is tris(2pyridylmethyl)amine (TPA). As will be explained shortly, the amine can interact with copper salts to form a soluble copper-amine ligand complex. The synthesis of TPA 279 was relatively straightforward using Geden's method. ${ }^{162}$

### 3.1 Reaction of parent compound 278a with copper (I) salt/ TPA complex

As previously mentioned in Scheme 67 initial work on substituted arylsulfonamides 278 using copper (I) salts and tren ${ }^{154}$ showed that a rearrangement to 277 could take place. Later work using copper (I) salts and TPA 279 as ligand (instead of tren) improved yields. Consequently, a series of experiments were conducted using the phenyl substrate 278a as depicted in Scheme 73. Heating a mixture of sulfonamide 278a ( 1.0 eq.) with equimolar amounts of copper (I) bromide ( 1.2 eq .) and TPA 279 (1.2 eq.) in refluxing toluene for 48 hours, led to complete disappearance of starting material. Analysis of the crude NMR (see Appendix 1) showed two products in a ratio of 1:5. The minor component was identified as the rearranged amide 280a. The structure for 280a was determined by ${ }^{1} \mathrm{H}$ NMR as shown in Figure 3.

Scheme 73 Reaction of radical precursor with CuBr and TPA 279

## Chapter Two

## Figure $3 \quad{ }^{1} \mathrm{H}$ NMR assignment of phenyl rearranged amide

Analysis of the phenyl rearranged amide 280a was made by ${ }^{1} \mathrm{H}$ NMR. Characteristic data involved a multiplex 7.4-7.25 (5H) for aromatics. A singlet at 1.55 for the dimethyl groups $(6 \mathrm{H})$, and peaks characteristic of the $n$-butyl group (2.92 (t), 1.461.39 (quintet), 1.33-1.23 (sextet), 0.80 (t,). The $\mathrm{N}-\mathrm{H}$ group appeared as a broad singlet at 5.41 ppm . The major product Figure 4 showed four distinct aromatics peaks indicative of a cyclised product which was tentatively assigned as 287 .

287

## Figure $4 \quad$ Structure of the proposed cyclic sulfonamide 287

Mechanistically this would arise from cyclisation of the radical $\mathbf{2 8 8}$ into the aromatic ring to give $\mathbf{2 8 9}$ followed by re-aromatisation to furnish the cyclic sulfonamide $\mathbf{2 8 7}$ as depicted in scheme 74.

Scheme 74
Proposed mechanism for the formation of the cyclic sulfonamide 287

## Chapter Two

### 3.2 Purification of the radical products

The reaction of the phenyl derivative 278a was monitored by TLC, which showed two products tentatively identified as the cyclised product 287 and the rearranged amide 280a. Due to the close proximity in Rf values between the starting material 278a and the cyclic sulfonamide 287, determining the end point of the reaction was very difficult. Further difficulty involved visualisation of the products, which were present in minor quantities. Isolation of the cyclised and rearranged products was achieved using careful flash chromatograph and ${ }^{1} \mathrm{H}$ NMR analysis of individual column fractions.

### 3.3 Characterisation of cyclised material 287

While full characterisation data for 287 and 280a was obtained, the mass spectra (EI or LSIMS-FAB $)$ was lacking an $\mathrm{M}^{+}$for $287(\mathrm{RMM}=281.1086)$ and instead $\mathrm{M}^{+}-\mathrm{SO}_{2}$ was observed $(\mathrm{RMM}=217.1459)$. The extrusion of $\mathrm{SO}_{2}$ in mass spectrometry of cyclic sulfonamides is well known and examples where an $\mathrm{M}^{+}$cannot be found are present in the literature. Instead $\mathrm{M}^{+}-\mathrm{SO}_{2}$ was observed and reported. ${ }^{179}$ However, while there was precedent for the extrusion of $\mathrm{SO}_{2}$ in mass spectrometry, in order to be certain of the assignment of 287 a sulfur analysis was obtained. Theoretically, this should be $11.4 \%$, instead only $0.43 \%$ was detected indicating minimal sulfur. A CHN analysis was also obtained. Theoretically this should be C, 64.2; H, 7.2; N, 17.2 for 287 instead the values obtained were $\mathrm{C}, 74.2 ; \mathrm{H}, 8.6 ; \mathrm{N}, 6.0$. Thus it was very likely that no $\mathrm{SO}_{2}$ was present in the product $\mathbf{2 8 7}$, and that the $\mathrm{M}^{+}$peak at 217 is not $\mathrm{M}^{+}-\mathrm{SO}_{2}$, but the correct mass for the molecular ion. Another technique to determine the presence of sulfur may be the use of ${ }^{33}$ S NMR. ${ }^{180-181}$ However this was not attempted. The major disadvantage being the small gyromagnetic ratio (1/13 that of ${ }^{1} \mathrm{H}$ ) and low natural abundance $(0.75 \%)$, that makes determining the small quantity

## Chapter Two

of sulfur in the product $\mathbf{2 8 7}$ very difficult. An alternative approach for determining the sulfur analysis would be either ICP-Emission, at minimum of $50 \mu \mathrm{~g} / \mathrm{L}$ of sulfur or ICP-MS, at minimum of $500 \mu \mathrm{~g} / \mathrm{L} .{ }^{182}$ Other techniques not used but might be useful for analysis are ${ }^{15} \mathrm{~N}$ NMR ${ }^{183,184}$ or the use of ${ }^{17} \mathrm{O}$ NMR ${ }^{185}$ which might show a change in the carbonyl group. For amides, this is typically around 300 ppm when using dioxane as the NMR standard. The difficulty with ${ }^{17} \mathrm{O}$ NMR is again associated with low natural abundance $\left(0.037 \%\right.$ ) and sensitivity $10^{5}$ less than a proton. A literature search suggested that the ${ }^{13} \mathrm{C}$ NMR ${ }^{186}$ data for the current compound matched that for the known oxindole 290 (Figure 5). Based on these results, it would appear that the cyclised material was 290 and not 287 (see Appendix 2).

290

Figure $5 \quad$ Structure of the oxindole 290
Whilst this was not the expected result, it was clear that further work would be required in order to obtain the cyclic sulfonamides if they were needed for the future. These compounds are pharmacologically important. They have well-known diuretic, antihypertensive, and anticonvulsive properties. ${ }^{187}$ Although the cyclised sulfur compound 287 is not known, the related compound $\mathbf{3 0 2}$ has been reported in the literature. ${ }^{187}$ Treatment of $o$-nitrotoluene 291 (Scheme 75), with diethyl oxalate 292 in sodium ethoxide (generated in-situ from sodium metal and ethanol), led to $o$ nitrophenylpyruvic acid ethyl ester 293. Hydrolysis of the ester led to the $o$ nitropyruvic acid derivative 294. Treatment of 294 with hydroxylamine hydrochloride 295 furnished the o-nitropyruvic acid oxime 296. Hydrolysis and

## Chapter Two

decarboxylation of the oxime 296 with acetic anhydride yield the $o$ nitrobenzylcyanide 297. Hydrogenation of 297 with palladium on charcoal in absolute ethanol, and hydrogen gas at $50 \mathrm{Ib} / \mathrm{psi}$ atmosphere furnished the $o$ aminobenzylcyanide 298. ${ }^{188}$ Diazoniation of 298 from sodium nitrite and hydrochloric acid, followed by addition of sulfur dioxide and copper(II)chloride led to the $o$-sulfonyl chloride derivative 299. Treatment of 299 with $n$-butylamine 282 furnished the arylsulfonamide derivative 300. Hydrolysis of the nitrile group gave the acid derivative 301, and this was followed by acid-induced cyclisation to give the cyclic sulfonamide 302. ${ }^{189}$

## Scheme 75 Synthesis of the cyclic sulfonamide precursor

Theoretically it should be possible to methylate $\mathbf{3 0 2}$ to the cyclic sulfonamide 287 as depicted in Scheme 76, which would allow Clark and Murphy to unambiguously determine if this product was presenting the crude NMR of 290. This synthetic approach however proved too lengthy (nine steps) ${ }^{187-189}$ and was not undertaken.

## Chapter Two

Consequently, the structure of the oxindole $\mathbf{2 9 0}$ has been confirmed by comparison to the literature data. ${ }^{190}$

Scheme 76 Methylation of the sulfur precursor 287

### 3.4 Potential mechanism for oxindole formation

Other groups have noted extrusion of $\mathrm{SO}_{2}{ }^{151}$ during cyclisation of sulfonamides. In the following example, vinylic sulfonamide $\mathbf{3 0 3}$ (Scheme 77) when treated with tributyltin hydride and AIBN furnished the aryl radical intermediate 304. This could undergo a 1,6-exo attack onto the alkene to form the cyclic radical intermediate $\mathbf{3 0 5}$. Ring opening followed by extrusion of sulfur dioxide led to the amidyl radical intermediate 306. Addition of the amidyl radical via 1,5-exo attack onto the alkene gave the oxindole radical intermediate $\mathbf{3 0 7}$, which followed by H -abstraction of tributyltin hydride formed the oxindole derivative 308.

## Chapter Two

Scheme 77 Motherwell's synthesis of an oxindole from sulfonamide
Motherwell has shown that radical cyclisation of vinylic sulfonate 309 (scheme 78) occurs similarly to give the 6-exo-product $\mathbf{3 1 1}$ in $70 \%$ yield, along with a minor amount of the ring contracted ether $\mathbf{3 1 0}$ in $5 \%$ yield via extrusion of $\mathrm{SO}_{2} \cdot{ }^{152}$ However, no analogous pathway to these observations is available in the current reaction to give oxindole 290.

Scheme 78 Motherwell's cyclic ether synthesis via $\mathbf{S O}_{2}$ extrusion
Alternatively, the oxindole $\mathbf{2 9 0}$ may be formed by direct cyclisation of the amidyl radical. ${ }^{191}$ In the following example, xanthate 312 (Scheme 79) when treated with dilauroyl peroxide generated the alkyl radical 313, which underwent an

## Chapter Two

intermolecular attack onto the alkenyl group of the $N$-allylsulfonylamide 314. This was followed by formation of the $N$-amidosulfonyl radical intermediate $\mathbf{3 1 5}$ and extrusion of sulfur dioxide to give the amidyl radical intermediate $\mathbf{3 1 6}$ followed by rapid 5-exo cyclisation onto the terminal alkene to furnish the lactam radical intermediate 317. The radical intermediate $\mathbf{3 1 7}$ can undergo addition to another molecule of $\mathbf{3 1 2}$ to give the lactam $\mathbf{3 1 8}$ and regenerating the radical 313, which could undergo the whole radical process described above.

## Scheme 79 Zard's synthesis of pyrrolidines through sulfonamides

Consequently in the current reaction, the oxindole 290 (Scheme 80) may be formed by cyclisation of the amidyl radical 322 generated from the tertiary radical $\mathbf{3 1 9}$ via 1,5-ipso cyclisation and re-aromatisation to give 321 followed by loss of $\mathrm{SO}_{2}$. Addition of the amidyl radical onto the aromatic ring followed by oxidation (presumably via $\mathrm{Cu}(\mathrm{II}) \mathrm{Br}_{2}$ ) would yield the oxindole 290.

## Chapter Two

## Scheme 80 proposed synthetic approach to oxindole

Alternatively, it may be possible that oxindole $\mathbf{2 9 0}$ forms via extrusion of $\mathrm{SO}_{2}$ directly from the cyclic sulfonamide 287 as depicted in scheme $\mathbf{8 1}$.

Scheme 81 Proposed synthetic approach to oxindole
It should be possible to determine which of these two mechanisms is operating if a substitutent is appended to the aromatic ring. This is because both mechanisms lead to different regioisomeric oxindoles (Scheme 82).

## Scheme 82 Proposed mechanisms for regioisomers

## Chapter Two

The final solution would be to complete an unambiguous synthesis of each of the regioisomers themselves. However, before this mechanistic curiosity could be addressed, it was necessary to a) determine if this was a general reaction, b) optimise the reaction conditions to increase the yield of the reaction, and $\mathbf{c}$ ) observe if it was possible to alter the ratio of the two products under different conditions.

An investigation towards the reaction of the phenyl derivative 278a (Scheme 83) under two experimental constraints were made. The first was to investigate the amount of copper (I) bromide and TPA 279 required to give complete conversion of the radical precursor 278a to products, and establish the effect on product outcome. Secondly, the role of using different temperatures to determine product outcome was studied as depicted in Table 3. For these experiments, both toluene and dichloromethane were used as these solvents are common solvents in ATRC. Typical experimental conditions are as follows: To a small three-necked flask was added the radical precursor 278a (1.0 eq.), copper (I) bromide (1.2 eq.) and TPA 279 (1.2 eq.). Toluene or dichloromethane was added via syringe. The reaction mixture was heated under a nitrogen atmosphere at reflux for a specified time. The reaction was quenched with ethyl acetate and the solvent evaporated in-vacuo to yield a brown or green crystalline solid. The crude product was obtained using ethyl acetate as the eluent and filtered through a silica plug to remove the inorganic copper residue.

## Chapter Two

Scheme 83 Phenyl sulfonamide radical reaction

| Entry | Reaction conditions | Conversion | Mass | Ratio |
| :--- | :--- | :---: | :---: | :---: |
| 278a |  | $\%$ | balance \% | $\mathbf{2 8 0 a : 2 9 0}$ |
| I | PhMe, rt, 96 h | $\mathbf{0}$ | 100 | $\mathbf{0 : 0}$ |
| II | DCM, rt, 168 h | $\mathbf{3 3}$ | 65 | $\mathbf{1 : 0}$ |
| III | PhMe, $50^{\circ} \mathrm{C}, 18 \mathrm{~h}$ | $\mathbf{1 2}$ | 83 | $\mathbf{1 : 1}$ |
| IV | $\mathrm{DCM}, 37{ }^{\circ} \mathrm{C}, 18 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 78 | $\mathbf{1 . 4 : 1}$ |
| V | $\mathrm{PhMe}, 110^{\circ} \mathrm{C}, 12 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 72 | $\mathbf{0 . 3 : 1}$ |
| VI | $\mathrm{PhMe}, 110^{\circ} \mathrm{C}, 48 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 66 | $\mathbf{0 . 2 : 1}$ |

Key: Mass balance is defined here as the mass of the crude product isolated, divided by the mass of radical precursor 278a used, expressed as a percentage. Conversion is defined here as the amount of [cyclised:rearranged] product obtained in the reaction minus the radical precursor, i.e. no radical precursor in $\mathrm{NMR}=100 \%$ conversion to products.

Table 3 Table for the parent substrate 278a in solvents at varying temperature [I]: At room temperature, the $\mathrm{CuBr} / \mathrm{TPA}$ ligand complex was insoluble in toluene and that the temperature was insufficient to generate a reaction. Consequently, only starting material was re-isolated (100\%).
[II]: In order to determine if a more polar solvent such as dichloromethane (DCM) would increase the solubility of the $\mathrm{CuBr} / \mathrm{TPA}$ complex ligand $(\mathbf{L})$ and thus facilitate the reaction at room temperature, the solvent was changed for this reaction. Notably under these conditions it was possible to mediate the reaction, however, it was relatively slow [67\% starting material remained after 168h]. Moreover, only the

## Chapter Two

product assigned as the rearranged amide 280a was detected, no oxindole $\mathbf{2 9 0}$ was isolated. The increase in solubilization of the $\mathrm{CuBr} / \mathrm{TPA}$ ligand complex $(\mathbf{L})^{192}$ is important in facilitating this reaction. The solvent can also change the redox potential of $\mathrm{Cu}(\mathrm{I}) / \mathrm{Cu}(\mathrm{II})$ salts, ${ }^{193}$ and by participating in bonding to the copper ligand complex geometry. ${ }^{194}$ Thus in DCM there may be a change in redox potential which helps to facilitate carbon-bromide bond homolysis. This eventually leads to the rearranged product 280 (and cyclised product). Electrochemical studies ${ }^{195}$ using cyclic voltammetry have provided proof that a change in redox potential occurs with different solvents.
[III]: Heating in PhMe for 18 h at $50^{\circ} \mathrm{C}$ did facilitate the reaction although it proceeded slowly, with only a small amount ( $12 \%$ conversion) of two products being produced in roughly 1:1 ratio, although the inaccuracy of this measurement is large due to small amounts of material in the crude NMR and the errors in integration of ${ }^{1}$ H NMR signals. The formation of an equal amount of the cyclised product $\mathbf{2 8 0}$ and the rearranged amide 290 would indicate that the $\mathrm{CuBr} / \mathrm{TPA}$ ligand complex was more active than in experiment $\mathbf{I}$. This is presumably due to the increased temperature at which the reaction was conducted leading to better solubility of the Cu complex.
[IV] Having observed that the reaction proceeded, and a possible selectivity for the rearranged product 280a in DCM at RT, the next task was to increase the temperature, in order to force the reaction to completion. Thus heating at $37^{\circ} \mathrm{C}$ for 18 h allowed the reaction to go to completion, although now the major product was the rearranged 280a instead of the cyclised $\mathbf{2 9 0}$ product. In this reaction, the increase in temperature has improved the solubilisation of the ligand complex and also the rate of reaction. The selectivity towards the rearranged amide, might be due to more

## Chapter Two

efficient H -abstraction of the amidyl radical intermediate $\mathbf{3 2 2}$ from dichloromethane of higher temperatures. This hypothesis could be tested by using a poor hydrogen donor as the solvent under the same conditions (i.e. tert- BuOH ) or increasing the temperature further.
[V]: The previous reactions with toluene [I] and [III] showed very poor turnover and solubility of the ligand complex. When the reaction was repeated in refluxing toluene for 12 hours the reaction proceeded to completion, but now the cyclised product 290 predominated. The reaction was shown to be complete ( $100 \%$ conversion) producing the two compounds 280a/290 in a $0.3 / 1$ ratio. The increase in temperature has improved the rate of reaction as expected. However contrary to the reaction in toluene the oxindole now predominates indicating that the rate of cyclisation is greater than H -abstraction in toluene at higher temperature
[VI]: In order to determine whether an increase in time would alter the product distribution (i.e. to determine if the reaction was under kinetic or thermodynamic control), the reaction was repeated in refluxing toluene for 48 hrs instead of 12 hrs . However, heating for 48 hours (four times the length as in entry $\mathbf{V}$ ) furnished only a similar yield and ratio of products, $0.2 / 1$ (within the level of accuracy of measurement by NMR). This would indicate that increasing the time does not change the outcome in terms of either selectivity or overall yield. This suggests either the reaction is under kinetic control or the reaction has reached its thermodynamic equilibrium after 12 hrs . Experimental work should be conducted to determine the precise time taken for complete conversion to products.

## Summary:

The results indicate that $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ is a superior solvent with respect to the rate/conversion of the reaction than toluene is at the same temperature. This is

## Chapter Two

presumably due to the improved solubility of the $\mathrm{CuBr} / \mathrm{TPA}$ complex in this solvent. Conducting the reaction at higher temperatures appears to increase the proportion of cyclic material with DCM at $37^{\circ} \mathrm{C}$, preferentially giving rearranged amide 280a while toluene at $110{ }^{\circ} \mathrm{C}$ preferentially furnished oxindole 290 . This was interesting since similar work by Speckamp ${ }^{145}$ on related systems has shown that lower temperatures generally led to cyclised products (anisole, RT, 24h), while rearranged amides were furnished with elevated temperatures (diphenylether, $190{ }^{\circ} \mathrm{C}, 0.5 \mathrm{~h}$ ). Having shown that the product ratio was sensitive to temperature the following experimental work involved investigating the effect of five further solvents, notably methanol, THF, MeCN, $\mathrm{H}_{2} \mathrm{O}$, BMIM $\mathrm{BF}_{4}$ (a common ionic liquid), all at the same temperature (Table 4).

[^0]Table 4: Effects of solvent on product distribution.

## Chapter Two

## Brief observations:

[VII]: The solubility of the copper ligand complex (L) was improved relative to both toluene and DCM using methanol but NMR analysis showed that the reaction had only gone to $66 \%$ completion after 18 hours and that it showed significant amounts of uncharacterised by-products.
[VIII]: In the copper ligand complex (L) was readily solubilised. The reaction was faster than in MeOH , with analysis showing the reaction had gone to $88 \%$ completion after 18 hours. It was also cleaner than in MeOH with no by-products detected.
[ $\mathbf{X}]$ : In this experiment deionised water was degassed with nitrogen for fifteen minutes. Excellent solubility was observed with the copper ligand complex (L). There was complete conversion to products. However minor amounts of similar byproducts to those detected in MeOH were produced.
[IX]: Acetonitrile readily solubilised the copper ligand complex ( $\mathbf{L}$ ). Acetonitrile is often the choice solvent for ATRC reactions, however the reaction was not clean giving significant amounts of unidentifiable products which precluded all efforts to separate them in order to glean spectroscopic information.
[XI]: $N$-butyl- $N$-methyl imidazolium tetrafluoroborate was used as an ionic liquid in order to investigate the effects of a polar environment. There was complete conversion to products under these conditions and this was selective towards the cyclised material 290 although the low mass balance was disappointing and was due to difficulty in extracting the products from the ionic liquid.

While all these solvents were able to facilitate the reaction to a certain extent, the reactions were messy with numerous compounds being produced in addition to the compounds of interest (Appendix 3). Ligand complex solubility was markedly

## Chapter Two

improved in all the solvents compared relative to toluene; however, they did not enhance the selectivity for either of the products $\mathbf{2 8 0} \mathbf{a} / \mathbf{2 9 0}$ to a synthetically useful level. The exception was THF, which was cleaner and gave the ratio of 280a/290 as $2 / 1$ although only to $88 \%$ conversion. There were some difficulties with extraction of the crude products from some of the solvents. With highly solubilised ligand complex, the light green copper (II) bromide is sometimes present along with the crude products. This is evident from the ${ }^{1} \mathrm{H}$ NMR which shows peak broadening due to paramagnetic $\mathrm{Cu}^{2+}$ ions $\left([\mathrm{Ar}] 3 d^{9}\right) .{ }^{196}$

Although not fully characterised, it seems that the minor components (uncharacterised by-product) consist of 286a, the corresponding sulfonamide 283a and the reduced ${ }^{178}$ product $\mathbf{3 2 3}$ (Figure 6). It became clear that the cleanest reactions with the best mass balance involved using either DCM or toluene.

323

## Figure 6 Phenyl reduced product 323

The most probable explanation for the formation of the reduced product $\mathbf{3 2 3}$ from some of the reactions would be H -abstraction from the solvent by radical 319 (Scheme 84). An alterative mechanism would be via an initial intramolecular 1,5-H abstraction $\mathbf{3 1 9}$ to $\mathbf{3 2 4}$ followed by reduction of $\mathbf{3 2 4}$ by the solvent.

## Chapter Two

## Scheme 84 Potential mechanism for the reduced product 323

Other reactions that could come from the secondary alkyl radical intermediate $\mathbf{3 2 4}$ could give further products that may be contained in the uncharacterised mixture of products. Thus a 1,5-ipso attack of $\mathbf{3 2 4}$ to furnish the cyclohexadienyl radical intermediate 325, followed by re-aromatisation and extrusion of sulfur dioxide to give the amidyl radical intermediate $\mathbf{3 2 6}$ could occur (Scheme 85). At this juncture, the amidyl radical intermediate $\mathbf{3 2 6}$ can be quenched via the solvent to give the rearranged amide $\mathbf{3 2 7}$ or undergoes cyclisation into the aromatic ring, followed by oxidation to the oxindole 328. Alternatively, the alkyl radical intermediate can undergo direct addition into the aromatic ring to furnish the cyclic sulfonamide 329, followed by loss of sulfur dioxide and subsequent amidyl radical addition into the aromatic ring to furnish 328 .

## Chapter Two

Scheme 85 Proposed mechanism based on 1-5 ipso and direct cyclisation

### 4.0 Use of tosyl sulfonamide 278e and mechanistic insights into oxindole formation

Having investigated the effects of the copper (I) bromide-TPA ligand on the neutral phenyl derivative 278a, and determining that under certain solvent conditions, that it was possible to obtain either the rearranged amide 280a or the cyclised product 290, attention was turned to substrates with varying groups on the sulfonamide aromatic ring. The purpose was to determine the effect of the copper (I) bromide-TPA and solvent effects on product outcome. The first substrate investigated was the tosyl derivative 278e (Figure 7).

Figure $7 \quad$ Structure of the tosyl radical precursor 278e

## Chapter Two

### 4.1 Introduction

Early work by Clark and Fullaway ${ }^{163}$ showed reacting 278e CuBr and various amine ligands could furnish the rearranged amide 280e and a cyclised product initially proposed as the cyclic sulfonamide 332. A series of amine ligands were used in conjunction with $\mathrm{Cu}(\mathrm{I}) \mathrm{Br}$ to form the ligand complex ( $\mathbf{L}$ ). The first experiment involved reaction of 278e, bipyridine ( 2.0 eq.) and CuBr ( $2.0 \mathrm{eq}$. ) in dichloromethane to furnish exclusively the rearranged amide 280e but only in $26 \%$ yield. The following reaction involved using pentyl-pyridin-2-ylmethyleneamine 330 (3.0 eq.) and CuBr (2.0 eq.) in dichloromethane. Again only the rearranged amide was isolated in poor yield (21\%). Further work involved using [1,10]-phenanthroline 331 ( 2.4 eq.) and CuBr ( 1.2 eq.) in dichloromethane gave no reaction. The reaction conditions were improved when equimolar amounts of tris(2-pyridinylmethyl) amine (TPA) and CuBr in dichloromethane ( 30 mL ) were used. In this case, the rearranged amide was produced in good yield (56\%). Remarkably, when the reaction was repeated with equimolar amounts of TPA and CuBr in dichloromethane ( 5 mL ) this led to a cyclic product that was believed to be the cyclic sulfonamide 332 and the rearranged amide 280e in $54 \%$ yield. The only difference in reaction conditions being one of concentration.

Scheme 86 Fullaway's synthesis of rearranged amide and cyclic product

## Chapter Two

Mass Spectrometry of the cyclic compound $\mathbf{3 3 2}$ showed an $\mathrm{M}^{+}(\mathrm{RMM}=231)$, which was contrary to the expected $\mathrm{M}^{+}(\mathrm{RMM}=295)$. This could only occur from $\mathrm{M}-\mathrm{SO}_{2}$, indicating that it was most likely the oxindole 333 (Figure 8) and that the Clark group ${ }^{165}$ had wrongly assigned the cyclic compound as $\mathbf{3 3 2}$ and not as oxindole 333 . No elemental analysis was done, nor an unambiguous synthesis of the sulfur compound $\mathbf{3 3 2}$ or oxindole $\mathbf{3 3 3}$ to adequately prove the structure of the cyclic compound. Consequently, the next step was to re-investigate this reaction.

333

## Figure 8 Structure of oxindole 333

In the previous section, it was postulated that there were two possible mechanisms (Scheme 82) for the formation of the oxindole product 290 and that carrying out the reaction would allow determining which of these two mechanisms is operational. Thus the reaction of the tosyl analogue $\mathbf{2 7 8 e} \mathrm{CuBr} / \mathrm{TPA}$ was further investigated. The presence of the para-methyl substituent would give a structural handle to determine how the reaction proceeds. If the mechanism goes via extrusion of $\mathrm{SO}_{2}$ from the cyclised compound, $\mathbf{3 3 4}$ then oxindole ${ }^{190}$ isomer $\mathbf{3 3 3}$ would be produced, if the oxindole occurs from cyclisation of the amidyl radical 335, the alternative oxindole isomer 336 should be detected.

## Chapter Two

Scheme 87 Proposed mechanisms for the oxindoles 333 and 336
Reacting bromide 278e with copper bromide/TPA in PhMe at reflux for 24h [I] furnished three products in a combined $94 \%$ overall yield. Chromatography of the mixture separated the rearranged amide 280e but the other two compounds eluted together. These two inseparable compounds were tentatively identified as the two possible oxindole regioisomers $\mathbf{3 3 3 : 3 3 6}$ in a 0.03:1 ratio.

### 4.2 Proposed methods for separation of regioisomers

In order to unambiguously assign the structures of the cyclised products it was necessary to separate them. However, several problems were encountered with separating these products, due to the close proximity of the Rf valves of the radical precursor 278e and both the desired cyclic compound(s) $\mathbf{3 3 3}$ or $\mathbf{3 3 6}$. The use of flash chromatography to isolate the products pure through individual column fractions was not sufficient to separate the regioisomers. Several methods have been used to prove regioisomeric oxindole structure and there has been some success in separating oxindole mixtures (by other researchers).

## Chapter Two

## Structure determination.

* NMR spectroscopic techniques ${ }^{197}$ for determining regioisomeric oxindoles:
(1) $\mathrm{NOE}^{198}$
(2) $\mathrm{HMBC}^{198}$
(3) HETCOR ${ }^{199}$
(4) INEPT $^{199}$
(5) $\operatorname{COSY}^{199}$
INADEQUATE. ${ }^{200}$
* (1) X-Ray Diffraction, ${ }^{201}$ X-Ray Crystallography ${ }^{202}$

## Separation

* Separation techniques for isolating regioisomeric oxindoles: (1) ReversePhase Column Chromatography, ${ }^{203}$ (2) HPLC-UV detector ${ }^{203}$ (3) ReversePhase HPLC, ${ }^{204}$ (4) GLC ${ }^{204}$ (5) MPLC. ${ }^{205}$
* Capillary Electrophoresis ${ }^{206}$

However while the methods could have been used to separate the products, ultimately an unambiguous synthesis of both of them was required.
a) Preparative TLC was used for small quantity of products ( $<100 \mathrm{mg}$ ), unfortunately, the products could not be separated because the Rf values were too close.
b) Preparative HPLC was available at Warwick, although due to high demand, it was not possible to use this method continuously.
c) GLC was available at Warwick, but again due to high demand, it was not possible to use this method continuously.

One main problem with the separation and identification of the regioisomeric oxindoles was the low yield that they were isolated in. The maximum obtained was 50mg. An INADEQUATE experiment was attempted, but failed to provide good spectra, due to insufficient products.

## Chapter Two

### 4.3 Radical reaction of tosyl precursor 278e

The identification of the major cyclised compound was accomplished by synthesising the oxindole $\mathbf{3 3 3}$ unambigiously. This was achieved using a modification of the Stollé synthesis (Scheme 88). In the original method, Stollé ${ }^{207,} 208$ had reacted $\alpha$-chlorocarboxylic acid chlorides with alkylated anilides to furnish precursors $\mathbf{3 3 7}$ for intramolecular Friedel-Craft alkylation reactions. The intramolecular Friedel-Craft alkylation was mediated using aluminium chloride to furnish the oxindoles 338 .

Scheme 88 Stollé synthesis
For 333 a variation to this approach was used, ${ }^{209-212}$ namely preparing the related bromo-analogue 341 as outlined in Scheme 89.

Key: (a) (i) NaH, DMF, (ii) n-BuI, RT, 24h; (b) TEA, 284, RT, 3h; (c) $\mathrm{AlCl}_{3} \mathrm{Anh} .50^{\circ} \mathrm{C}$ at 10 min . then $160^{\circ} \mathrm{C}$ at 60 min .

## Scheme 89 Synthetic route toward the oxindole 333

## Chapter Two

This approach was used to prepare a sample of the oxindole $\mathbf{3 3 3}$ although some hydrolysis of the amide bond in $\mathbf{3 4 1}$ occurred under the reaction conditions. With 333 in hand, it was possible to determine that this oxindole was the minor component of the two cyclised products (1:0.03) obtained in the copper-mediated reaction of 278 e.

### 4.4 Attempted synthesis of the major oxindole 336

In order to be certain that the major cyclised product resulting from the coppermediated reaction was the regiomeric oxindole 336 it was necessary to make an authentic sample of this compound as well. The outline of the synthesis is shown in Scheme 90. The oxindole $\mathbf{3 3 6}$ was prepared using the same procedure as used for the minor product 333. Although two regioisomers 346 and 336 were obtained (again inseparable), the proton NMR spectra obtained from this crude mixture, tentatively shows the product from the copper reaction to be the oxindole 336, (see Appendix 4). Whilst it cannot be said with $100 \%$ certainty, it is likely that the major cyclised product is the oxindole $\mathbf{3 3 6}$ due to these spectral similarities. This would have been formed via the amidyl radical intermediate $\mathbf{3 3 5}$ cyclising onto the aryl ring ( $\mathbf{3 3 5}$ to 336 as depicted in Scheme 87. Due to time constraints, it was not possible to repeat this experiment. The methyl analogue of oxindole $\mathbf{3 3 6}$ has been synthesised by Nishio's ${ }^{178}$ group (Figure 9) and NMR was consistent with assignment of $\mathbf{3 3 6}$.

Figure $9 \quad$ Structure of Nishio oxindole 342

Key: (a) (i) NaH , DMF, (ii) n-BuI, RT, 24h; (b) TEA, 284, RT, 3h; (c) $\mathrm{AlCl}_{3} \mathrm{Anh} .50^{\circ} \mathrm{C}$ at 10 min . then $160^{\circ} \mathrm{C}$ at 60 min .

Scheme 90 Synthesis of oxindole 336

### 4.5 Authentic synthesis of the rearranged amide 280 e

Having proven the identity of the two oxindoles $\mathbf{3 3 3}$ and $\mathbf{3 3 6}$ the next step was to prepare an authentic sample of the rearranged amide $\mathbf{2 8 0 e}$ for comparison with that obtained from the reaction of 278e. This approach involved the dialkylation of the known ester 347. ${ }^{213-216}$

## Scheme 91 Synthesis of the di-methylated product 348

The first method for dialkylation investigated involved treating the ester 347 with sodium hydride ( 2.2 eq .) in anhydrous THF followed by iodomethane ( 2.2 eq .) at

## Chapter Two

room temperature for 48 hours (Method A). ${ }^{216-217}$ Analysis of the crude reaction mixture by NMR showed that the reaction had failed to provide 348, and that only a monomethylated product 349 had been formed. In order to push the reaction to completion, the monomethylated product 349 was re-exposed to the reaction conditions (i.e. treated with sodium hydride (1.2 eq.) and iodomethane ( 2.0 eq. ) at RT for 24 hours). The crude NMR analysis again showed only the monomethylated product 349. This indicated that the second alkylation was slow presumably due to alkylation of a tertiary carbon. The next step involved modifying the reaction so the ester $\mathbf{3 4 7}$ was treated with sodium metal chips ( 3.0 eq ) in anhydrous ethanol ( $95 \%$ ), and iodomethane ( 3.0 eq.) at RT for 48 hours (Method B). The crude NMR again showed only the monomethylated product 349 . Thus, it seems that the second alkylation was particularly slow under these conditions as well. In light of these problems, a stronger base was used. The ester $\mathbf{3 4 7}$ was treated with $n$-butyllithium (1.6M) (2.2 eq.) in anhydrous THF, followed by iodomethane (2.2 eq.) (Method C). While successful in part (both $\mathbf{3 4 8}$ and $\mathbf{3 4 9}$ were produced as indicated by NMR data of the crude reaction mixture) the reaction did not provide enough 349 to continue.

An alternative procedure to Method A was next used. The ester 347 was treated sodium hydride (3.6 eq.) in anhydrous DMF and iodomethane (3.6 eq.) (Method D). Distillation of the crude product gave a mixture of $\mathbf{3 4 8}$ and 349. Further purification using flash chromatography separated the desired dialkylated ester, albeit in low yields ( $6 \%$ ). The reaction was repeated using sodium hydride ( 3.0 eq.) in the more polar DMF and iodomethane ( 3.0 eq.). The ester 347 was added dropwise to the suspension over one hour (Method E). ${ }^{219}$ Again chromatography was required after initial distillation and gave the dialkylated product 347 in slightly better yield (20\%).

## Chapter Two

The gem methylated ester 348 was next subjected to hydrolysis with ethanolic potassium hydroxide solution to give the acid $\mathbf{3 5 0}^{220}$ in $74 \%$. This was followed by conversion to the acid chloride $\mathbf{3 5 1}$ in $31 \%$ yield using excess oxalyl chloride. The amide $\mathbf{2 8 0}$ e in $84 \%$ was then prepared from the acid chloride $\mathbf{3 5 1}{ }^{221-222}$ with excess butylamine 282. The spectroscopic details matched those of the product isolated from the copper mediated reaction (Scheme 87).

## Scheme 92 Synthesis of the rearranged amide 280e

### 4.6 Reaction of tosyl substrate 278 e in various solvents

As is the case from the previous reaction of the phenyl radical precursor 278a, evidence of both cyclised products and rearranged amide was presented. The next step was to determine the effects of solvent on the substrate 278e and see if it was similar to that observed with 278a. In this reaction, the methyl group would be weakly electron donating, and this effect would indicate the effect on cyclisation and rearrangement with respect to the parent precursor 278a.

## Chapter Two

## 5.0 $\quad N$-Butyl-2, 4, 6-trimethyl-benzenesulfonamide $278 f$

Having established that reaction of both 278a and 278e led to both rearranged and oxindole formation, the following experiment involved investigating the reaction of the mesitylene sulfonamide 278f. The presence of the ortho methyl groups ensures that no oxindole can be formed but theoretically allowing only the rearranged compound to be produced 280f. However, the presence of the ortho methyl groups is also likely to retard the rate of formation of the rearranged amide $\mathbf{2 8 0 f}$ due to increased steric hinderence for the ipso attack at the aromatic sulfonamide carbon. No reaction was obtained upon heating in toluene at $50^{\circ} \mathrm{C}$ for 18 h (this should be compared to $46 \%$ conversion of the tosyl analogue 278e under these conditions). Interestingly it was possible to convert $\mathbf{2 7 8 f}$ to the desired $\mathbf{2 8 0 f}$ if the reaction was run in the ionic liquid $\mathrm{BMIM} \mathrm{BF}_{4}$. Although the reaction indicated no starting material, only a $25 \%$ isolated yield of $\mathbf{2 8 0 f}$ was obtained (Table 6). Poor yields were attributed to difficulty in isolating the product from the ionic liquid.

Table 6 Effects of reaction conditions on product distribution for $278 f$

## Chapter Two

The exact reason why the ionic liquid is successful in this reaction is not fully understood, and further research will need to be undertaken. However, the use of the same ionic liquid in conventional 1,5-exo ATRC reactions leads to significant rate enhancement. ${ }^{223}$

## 6.0 $\quad N$-Butyl-2-naphthylsulfonamide 278 g

Previous work by Speckamp ${ }^{147}$ has shown that when the 2-naphthyl substrate $\mathbf{2 4 8}$ was treated with tributyltin hydride and AIBN, the cyclised product 249 was obtained together with the reduced product 250. In light of these observations, an investigation toward the reaction of the analogous sulfonamide $\mathbf{2 7 8 g}$ involved using the sulfonamide 278g. NMR analysis (see Appendix 5) showed the rearranged amide $\mathbf{2 8 0} \mathrm{g}$ was produced in $44 \%$ yield. The reaction was messy and several unidentified products were produced as has been previously described with other substates.

Scheme 95 Speckamp's naphthalene sulfonamide radical reaction

Scheme 96 Radical reaction of naphthalene sulfonamide 278g

## Chapter Two

## 7.0 $\quad N$-Butyl-4-methoxy-benzenesulfonamide 278h

Having investigated the scope of the reaction with simple substrates, it was now decided to determine the effects of various electron donating and withdrawing aryl groups on the efficiency and selectivity of the mechanism. The first substrate to be examined involved the electron donating para methoxy derivative $\mathbf{2 7 8 h}$.

Scheme 97 Radical reaction of 4-methoxy sulfonamide 278h
Reacting the bromo radical precursor 278h with copper bromide/TPA in dichloromethane at $37{ }^{\circ} \mathrm{C}$ for 18 h [II] furnished 3 products in $73 \%$ overall yields. Chromatography separated two cyclised regioisomeric products 352 and 353 from the rearranged amide 280h obtained from individual column fractions. Upon ${ }^{1} \mathrm{H}$ NMR analysis of the cyclised products (Appendix 6), it was determined that the major cyclised product had similar ${ }^{1} \mathrm{H}$ NMR characteristics to the 6 -substituted oxindole 336. This would indicate that the major cyclised product was oxindole 352 (Figure 10) and might be produced via the same mechanistic pathway described in Scheme 87 (via the amidyl radical intermediate 335).

352

353

Figure 10 Structure of regioisomeric oxindoles 352 and 353

## Chapter Two

The minor cyclised product was tentatively assigned as the 5 -substituted oxindole $\mathbf{3 5 3}^{224}$ that was analogous to the previously synthesised oxindole 333. This could occur via the extrusion of sulfur dioxide mechanism as shown in Scheme 87. A minor compound tentatively assigned as the reduced product $\mathbf{3 2 3 h}$ was also isolated (Figure 11).

323h
Figure 11 Structure of possible reduced product 323h
Analysis of mass spectrometry using LSIMS-FAB showed an $\mathrm{M}^{+}$(100\%) at 248, which was consistent with the $\mathrm{M}^{+}$of the oxindole 352. An analogous compound to 353 was synthesised by Hartwig. ${ }^{224}$ (Figure 12) Spectroscopic data was similar to the minor oxindole $\mathbf{3 5 3}^{225}$

354
Figure 12 Hartwig's $N$-Me oxindole 354
An important observation was that the reaction appeared to be faster than for the tosyl derivative 278e ( $85 \%$ conversion under the same conditions). This trend was explored more thoroughly (Table 7). Initial studies using dichloromethane at $37^{\circ} \mathrm{C}$ for $3 \mathrm{~h}[\mathbf{I}]$ showed complete conversion to products. The reaction was repeated using toluene at $50^{\circ} \mathrm{C}$ [III] and $80^{\circ} \mathrm{C}$ [IV] for 18 h . Again, there was complete conversion to products (as a comparison 278e proceeded to $56 \%$ conversion under identical conditions to entry III). The ratio of products $\mathbf{2 8 0 h}$ to $\mathbf{3 5 2}$ from these reactions was

## Chapter Two

1:1. This agrees with the observed trend for the other substrates where DCM gives a better selectivity in favour of the rearranged products $\mathbf{2 8 0}$. As before an investigation of different solvents to determine the effect on product distribution was carried out. When the reaction was conducted in methanol at $50^{\circ} \mathrm{C}$ for 18 h [entry $\mathbf{V}$ ] only a slight increase in selectivity towards the rearranged amide $\mathbf{2 8 0 h}$ was observed (1.2:1) compared to toluene. However, when THF [entry VI] 280h was used at same temperature and time, complete selectivity for the rearranged amide was observed. The reason for this solvent effect is unclear but it was not observed when the phenyl (278a, Table 4) or tosyl (278e, Table 5) precursors were employed.

Scheme 98 Radical reaction of 4-methoxy sulphonamide 278 h

## Chapter Two

### 8.0 Effects of different halogens in the para position.

Speckamp ${ }^{226}$ has investigated the effect of halogen substitution in the para position on the related rearrangement of $\mathbf{2 3 5}$. Scheme 99. It was found that the ratio of products $\mathbf{2 3 6}$ and $\mathbf{2 3 7}$ was similar for the bromine and chlorine derivatives (1:1.2) whereas the fluoro derivative was similar to the parent (235, $\mathrm{X}=\mathrm{Y}=\mathrm{H}$ ) (1:0.6). A comparison of the fluoro derivative 278h was made with the parent compound 278a and a comparison of the results for bromo 278c and iodo 278d derivatives (the chloro derivative was unavailable for this study).

Key: (a) $\mathrm{X}=\mathrm{F}, \mathrm{Y}=\mathrm{H}$; (b) $\mathrm{X}=\mathrm{Br}, \mathrm{Y}=\mathrm{H}$; (c) $\mathrm{X}=\mathrm{Cl}, \mathrm{Y}=\mathrm{H}$

## Scheme 99 General reaction for Speckamp radical reaction

### 8.1 The fluoro radical precursor 278b

## Scheme 100 Radical reaction of 4-fluoro sulphonamide 278b

Heating the fluoro substrate in refluxing toluene for 18h [II] Table 8 showed after column chromatography two products, which upon NMR analysis were shown to be the cyclised product and the rearranged amide 280b. The NMR for the cyclised product showed only one product tentatively assigned as $\mathbf{3 5 5}$. Mass spectrometry showed an $\mathrm{M}^{+}$at 235 (85\%) indicative of an oxindole instead of the $\mathrm{M}^{+}=299$ for the

## Chapter Two

cyclic sulfonamide and elemental analysis of sulfur indicated $0.35 \%$ sulfur, where $10.7 \%$ was required for the cyclic sulfonamide 356 (Figure 13).

Scheme 101 Radical reaction of 4-fluoro sulfonamide 278b

356

## Figure 13 Structure of proposed fluoro compound 356

Due to the complex ${ }^{1} \mathrm{H}$ NMR spectra (Appendix 7), it was not possible to determine which regioisomers of the oxindole was the major material, and it was not possible to purify them further. A possible method would be to synthesis the two regioisomers as outlined in Schemes 89/90, page 112-114. It was observed that the ratio of

## Chapter Two

products for the fluoro substrate 278b and the phenyl derivative 278a were similar in refluxing toluene and dichloromethane (Entry I-IV).

### 8.2 The bromo and iodo radical precursors 278c-d

Heating the bromo substrate 278c, $\mathrm{X}=\mathrm{Br}$ in dichloromethane at $37{ }^{\circ} \mathrm{C}$ for 7 h furnished two products which were identified from NMR analysis as the rearranged amide 280c and a cyclised product 357 (Table 9). Careful chromatography separated the rearranged amide from the cyclised product; however, isolation of pure cyclised product was not achievable. The ${ }^{1} \mathrm{H}$ NMR spectra of the cyclised product indicated one cyclised product only, which was similar to the NMR of the 6 -substituted oxindole ${ }^{227} 336$.

Scheme 102 Radical reaction for 4-bromo and 4-iodo sulfonamides

Table 9: Effects of solvents/time on product distribution for the halogen substrates 278c-d.

An analogous compound to $\mathbf{3 5 7}$, namely $\mathbf{3 5 8}$ has been synthesised by Atwal et al. ${ }^{227}$ as shown in Figure 14.

## Chapter Two

358

## Figure 14 Atwal's structure of oxindole 358

Heating the iodo substrate 278d in dichloromethane at $37{ }^{\circ} \mathrm{C}$ for 7 h facilitated a similar outcome (although the reaction was messier with a range of by-products being formed) (Table 9). Once again, isolation of pure cyclised oxindole 359 was unachievable thus, it was not possible to ascertain with certainty which cyclised regioisomer product was present. However, the ratio of rearranged amide 280/cyclised 359 was similar to that obtained for the analogous bromo derivative (see Table 9). Following the interesting observation that heating the methoxy derivative 278h in THF led to the rearranged product selectively, this was repeated for one of the halogen derivatives 278c, Entry II. Although not completely selective this time when run in THF a larger selectivity for the rearranged product (2.4/1 to 13/1) was obtained. This may suggest that THF is a far better H -donar towards amidyl radicals than DCM or toluene. In fact as amidyl radicals are thought to be electrophilic radicals the polarity of abstraction (C,NCH, H-atom) from the $\alpha$ position of THF is electronically matched.

The rates of reaction between the parent sulfonamide 278a and the halogens 278b-d in DCM under copper(I)bromide/TPA conditions showed that the halogens reacted faster than the parent compound 278a.

### 9.0 Effects of para and meta electron-withdrawing groups

Having investigated the effects of electron donating groups and halogens, the next step was to investigate the electron withdrawing groups to determine (a) whether there was a similar trend in selectivity towards the rearranged amide 280 and

## Chapter Two

cyclised 360-363 products compared to the electron donating groups, and (b) and the effects of solvents on product distribution. Consequently, the following step was to investigate the electron withdrawing groups: the cyano compound 278i and nitro compound as $\mathbf{2 7 8 j}$ were the chosen substrates, both containing strong electronwithdrawing groups.

### 9.1 The cyano and nitro radical precursor 278i-j

Key: $\mathbf{2 7 9} \mathbf{i}=\mathrm{CN} ; \mathbf{2 7 9} \mathbf{j}=\mathrm{NO}_{2} ; \mathrm{R}=\mathrm{CN}=\mathbf{3 6 0}$ and $\mathbf{3 6 2}, \mathrm{R}=\mathrm{NO}_{2}=\mathbf{3 6 1}$ and $\mathbf{3 6 3}$
Scheme 103 Radical reactions of 4-cyano and 4-nitro sulfonamides
Heating the bromide 279i $(\mathrm{R}=\mathrm{CN})$ in dichloromethane at $37^{\circ} \mathrm{C}$ for 4 hours led to complete conversion to products. This was a significantly more rapid reaction than either the parent $(\mathrm{R}=\mathrm{H})$ or $p$-methoxy $(\mathrm{R}=\mathrm{OMe})$ substrate. The crude ${ }^{1} \mathrm{H}$ NMR showed two products the rearranged amide $\mathbf{2 8 0} \mathbf{i}$ and the cyclised product. Chromatography separated the rearranged amide from the cyclised product $\mathbf{3 6 4}$ with the rearranged amide 280i being obtained pure in good yield (60\%) (see Appendix 8). Only one cyclised product was present, and no minor cyclised product was observed as in the previous reactions. However, it was not possible to obtain the pure cyclised product due to co-elution with other minor by-products. In order to improve conditions, the bromide $\mathbf{2 7 8 i}$ was heated in refluxing toluene for 18 hours this time. The crude NMR showed three products identified as the rearranged amide $\mathbf{2 8 0 1}$ and the cyclised products 360 and 362 see Appendix 9). Chromatography separated the

## Chapter Two

rearranged product 280i from the two inseparable cyclised products $\mathbf{3 6 0}$ and $\mathbf{3 6 2}$ (0.2/1). Mass spectrometry showed an $\mathrm{M}^{+}$at 242 , which had the same mass as the oxindole $\mathbf{3 6 0 / 3 6 2}$ (Table 10). To be certain, a sulfur analysis was obtained. Sulfur analysis showed $0.35 \%$ sulfur instead of the theoretical $10.47 \%$ for the cyclic sulfonamide 364 (Figure 15).

364

Figure 15 Proposed minor cyclised sulfonamide 364

The CHN gave $\mathrm{C}, 74.3 ; \mathrm{H}, 7.8 ; \mathrm{N}, 11.6$, and the calculated oxindole was $\mathrm{C}, 74.1 ; \mathrm{H}$, 7.8; $\mathrm{N}, 11.0$. It was most likely that the cyclised products were the regioisomers of the oxindoles 360 and 362.

An analogous compound by Hartwig ${ }^{224}$ whereby a methyl group was used in place of the butyl group had similar NMR assignment and coupling constants, which showed that Hartwig's oxindole 365 (Figure 16) was similar to the minor oxindole 360. The major cyclised product was tentatively assigned as the meta oxindole $\mathbf{3 6 2}$.

365

Figure 16 Hartwig's structure 365

## Chapter Two

Scheme 104 Radical reaction of 4-cyano sulfonamide 278e

| Entry | Reaction | Conversion | Mass | Ratio |
| :---: | :---: | :---: | :---: | :---: |

Table 10: Table for the cyano substrate 278 i under various conditions using toluene and DCM.

Heating the nitro derivative $\mathbf{2 7 8 j}$ in dichloromethane at $37{ }^{\circ} \mathrm{C}$ for 2.5 h led to complete conversion to products (see Table 11). This reaction was even faster than for the $p$ - CN derivative 278i The crude NMR showed two products identified as the rearranged amide $\mathbf{2 8 0 j}$ and a cyclised product $\mathbf{3 6 6}$. The rearranged amide was obtained pure in fair yield (43\%). The cyclised product was obtained as only one regioisomer but it was impossible to obtain pure. The reaction was repeated under identical condition but for 4 h . This time the cyclised product 366 was isolated pure as one product, though in only trace amounts. In order to improve the cyclisation, the reaction was repeated for 24 h ; however now the crude NMR showed several products, which after chromatography led to two inseparable cyclised products (see Appendix 10) in a ratio of ( $0.5 / 1$ ) and the rearranged amide $\mathbf{2 8 0 j}$.

Scheme 105 Radical reaction of 4-nitro sulfonamide 278j

| Entry | Reaction | Conversion | Mass | Ratio |
| :---: | :---: | :---: | :---: | :---: |
| 278i-j | Conditions | $\%$ | Balance | $\mathbf{2 8 0} \mathbf{: 3 6 1 : 3 6 3}$ |
| I | $\mathbf{1 6 2} \mathbf{j}, \mathrm{DCM}, 37^{\circ} \mathrm{C}, 2.5 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 69 | $\mathbf{6 . 5 : 1 : 0}$ |
| II | $\mathbf{1 6 2 j} \mathrm{DCM}, 37^{\circ} \mathrm{C}, 4 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 74 | $\mathbf{4 : 1 : 0}$ |
| III | $\mathbf{1 6 2 j}, \mathrm{PhMe}, 110^{\circ} \mathrm{C}, 24 \mathrm{~h}$ | $\mathbf{1 0 0}$ | 54 | $\mathbf{1 . 3 : 0 . 5 : 1}$ |

Table 11 The effects of solvent, time and temperature on product distribution for nitro substrate 278j

Mass spectrometry using LSIMS-FAB showed an $\mathrm{M}^{+}$at 262 (100\%) for $\mathbf{3 6 1 / 3 6 3}$ which the mass of the oxindoles $\mathbf{3 6 1 / 3 6 3}$. To be certain, a sulfur analysis was obtained. Sulfur analysis showed $6.13 \%$ compared to theoretical sulfur $9.81 \%$ for the cyclic sulfonamide. CHN analysis was also obtained to determine whether this mixture contained the cyclic sulfonamide 366 (Figure 17). The theoretical content for the cyclic sulfonamide was $\mathrm{C}, 51.5 ; \mathrm{H}, 5.5 ; \mathrm{N}, 8.6$., compared to the isolated product, which was found to be $\mathrm{C}, 55.7 ; \mathrm{H}, 7.7 ; \mathrm{N}, 6.6$. It is unclear at present, if these inseparable mixtures of two cyclised compounds can be unambiguously assigned as the sulfonamide $\mathbf{3 6 6}$ and one corresponding oxindole. It is most likely that the high sulfur content could be attributed to the cyclic sulfonamide, since there is no evidence for any other known sulfur compound. The minor product would be

## Chapter Two

attributed to one of the oxindoles, but it is not possible to determine which oxindole as this would be from the crude NMR.

366

Figure 17 Proposed cyclic sulfonamide 366
The observation of a sulfur-containing compound was unexpected, since all compounds have shown minimum sulfur. The reason for this case is unclear and further study would be required. It is interesting to note that the reaction was rapid compared to the other compounds studied (2.5h). As in previous reactions, the cyclised compound predominated when refluxing toluene was used.

### 9.2 The trifluoromethyl and meta-3,5-trifluoromethyl radical precursors

 278k-IThe previous compounds 278i-j predominately led to the rearranged amides $\mathbf{2 8 0} \mathbf{i} \mathbf{- j}$ in dichloromethane at $37^{\circ} \mathrm{C}$. Although only seen as a minor by-product, a significant amount of the hydrolysed sulfonamide 283i-j (see page 86), was also isolated from these reactions. This maybe due to the electron withdrawing aryl group that would make hydrolysis of the sulfonamide more facile. Consequently, the next step was to study other compounds containing electron-withdrawing groups namely 278k-I (Scheme 106).

Scheme 106 Radical reaction of 4-trifluoromethylbenzenesulfonamide 278k

## Chapter Two

Heating the bromide 278k in dichloromethane at $37{ }^{\circ} \mathrm{C}$ for 4.5 h led to complete disappearance of the starting material. Again the reaction was more rapid than the parent $(\mathrm{R}=\mathrm{H})$ and $p$-methoxy $(\mathrm{R}=\mathrm{OMe})$ with a similar rate to $\mathrm{R}=\mathrm{CN}$. The crude ${ }^{1} \mathrm{H}$ NMR showed two compounds which were identified as the hydrolysed sulfonamide 283k (Figure 18) and the rearranged amide 280j (see Appendix 11). As before the electron-withdrawing nature of the sulfonamide led to significant decomposition. It was not possible to isolate a pure sample of the rearranged amide $\mathbf{2 8 0 k}$ as it co-ran with the hydrolysed sulfonamide $\mathbf{2 8 3 k}$.

Figure 18 Structure of trifluoromethylbenzenesulfonamide
The reaction was repeated under identical condition using THF instead of dichloromethane, since previous studies have shown that THF can enhance selectivity towards the rearranged amide 280. The crude NMR showed that the reaction had only gone to $50 \%$ conversion. Only the rearranged amide 280k was present, but isolation of pure 280k was now unsuccessful as it was impossible to separate from unreacted starting material $\mathbf{2 7 8 k}$. The next step was to investigate the 3,5-meta substrate $\mathbf{2 7 8 1}$ to determine the effect on product distribution. The bromide 2781 was heated in dichloromethane at $37^{\circ} \mathrm{C}$ for 1.5 h . Although recovered in only $67 \%$ after chromatography, there was only one product. This was identified spectroscopically as the rearranged amide 2801. No oxindole $\mathbf{3 6 7 / 3 6 8}$ were isolated (Table 12).

## Chapter Two

Table 12:
The effects of solvents, time and temperature on product distribution for the substrates 278k-l.

The use of the electron withdrawing substituents $\mathbf{2 7 8 1}$ has led predominately to the rearranged amide 2801 (see Appendix 12) when carried out in dichloromethane at $37{ }^{\circ} \mathrm{C}$. This also fits the trend found with the electron donating substituents 278a-h. However, in general, changing the solvent to toluene (in all the previous examples studied) leads to a reversal in selectivity. When 2781 was heated in refluxing toluene, this switch of selectivity away from the rearranged products, was also observed, (although now in equal ratios). Most intriguingly is the formation of one cyclised product $\mathbf{3 6 7 / 3 6 8}$. The use of strongly activated substrates such as the para trifluromethyl substrate 278k, p-cyano 278i and p-nitro 278j produced unexpected results as the formation of the large amount of hydrolysed sulfonamide 283i-k was

## Chapter Two

detected. This may arise due to the increased ease of hydrolysis of amides and sulfonamides with strongly electron withdrawing groups

### 10.0 Conclusion for chapter two

As can be seen the rate and ratio of products (rearranged amides and oxindoles) is dependent upon the electronic nature of the aryl substituent. The main product arises from rearrangement via 1,5-ipso cyclisation in all cases with the relative amount increasing for the strongly electron withdrawing and donating substituents (e.g. ratio H, F< 4-Br, 4-I, 2-naphthyl < 4- $\mathrm{NO}_{2}, 4-\mathrm{CN}<4-\mathrm{OMe}, 3,5-\mathrm{CF}_{3}$ ). The rates of reaction also seem to be influenced by the substituent with the rate following (2-naphthyl < $\left.\mathrm{H}, 4-\mathrm{CH}_{3}<4-\mathrm{I}, \mathrm{F}, 4-\mathrm{Br},<4-\mathrm{CN}, \mathrm{CF}_{3}<4-\mathrm{OMe}<4-\mathrm{NO}_{2},<3,5-\mathrm{CF}_{3}\right)$. The intermediate cyclohexadienyl radical $\mathbf{3 5 5}$ will be stabilised by both electron withdrawing and donating substitutents which should favour cyclisation and is reflected in this order. Furthermore, in these studies the effect of temperature and solvent on the reaction (278a for example), showed that at high temperature (toluene/110 ${ }^{\circ} \mathrm{C}$ ), the cyclised oxindole products 293 predominated (e.g. ratio rearranged/oxindole $=0.3 / 1.0$ ), whilst at lower temperature and in better H -donor solvents (dichloromethane $37{ }^{\circ} \mathrm{C}$ ) the rearranged product 293 predominated (e.g. ratio rearranged/oxindole $=1.4: 1.0$ ). For all substrates 278 when ran in DCM or THF, there is a greater selectivity towards the rearranged amide over the cyclised oxindoles (compared to toluene). Reduction of the intermediate amidyl radical intermediate $\mathbf{3 5 5}$ possibly occurs via hydrogen abstraction from the solvent and is likely to be faster than DCM/THF than from toluene. This is reflected in the increased ratio of rearranged products to cyclised products in these reactions. Identification of the cyclised products as oxindoles was achieved by preparing them authentically via alternative routes and by comparing their spectroscopic details to

## Chapter Two

those previously published. The major cyclised oxindole product appears to arise from the cyclisation of the intermediate amidyl radical and not $\mathrm{SO}_{2}$ extrusion from a cyclic sulfonamide intermediate.

## Further work

Further work could investigate the effect of the catalyst, concentration, on the reaction and try to develop conditions to optimise the oxindole products by retarding the rate of H -abstraction from the solvent by the amidyl radical intermediate.

An array of amine ligands should be tested. This would involve all amines used by the Clark group, in particular, the use of TMEDA proved successful for Wongtap's work ${ }^{156}$ (see Chapter three). Fullaway has had success with the pentyl-pyridin-2ylmethyleneamine ligand.

A series of experiments on ligand concentration should be investigated. In the case of the nitro derivative, using excess ligand may have generated the cyclic sulfonamide based on the high sulfur content from the S analysis.

In order to push the reaction towards cyclisation. A series of poor hydrogen donor solvents should be used. In theory, this should give exclusively cyclised products.

Each substrate must be treated differently, and several methods might be required to optimise the radical conditions.

### 1.0 Aims and Objectives

Having investigated the effect of the aryl group on the reaction outcome, a range of nitrogen substituents ( $\mathrm{R}^{1}$ ) $\mathbf{3 6 9}$ ranging from $1^{\circ}$ substituents of increasing length $\left(\mathrm{C}_{2} \mathrm{H}_{5}, \mathrm{C}_{3} \mathrm{H}_{7}, \mathrm{C}_{4} \mathrm{H}_{9}, \mathrm{C}_{5} \mathrm{H}_{11}, \mathrm{C}_{6} \mathrm{H}_{13}, \mathrm{C}_{12} \mathrm{H}_{25}\right)$ to branched alkyl groups (e.g. $i$ - $\mathrm{Bu},( \pm)-s-$ $\mathrm{Bu}, t-\mathrm{Bu}$ ) to chiral groups (R)-1-cyclohexyl, to extremely hindered (1-adamantyl) were chosen for investigation. In order to ascertain the effects of these substituents, the aryl group (tosyl) and initiation group $\left(\mathrm{CMe}_{2} \mathrm{Br}\right)$ were kept constant.

Scheme 108 General reaction scheme for $N$-alkyl substrates 369 with CuBr/TPA

### 1.1 Synthesis of radical precursors

The initial approach to furnish these compounds was identical to that described in Chapter 2. Thus, $p$-tosyl chloride 281e (1.0 eq.) was treated with the amine of choice 373a-k, (1.0 eq.) and triethylamine (1.0 eq.) in dichloromethane Method A or with just 3 equivalents of amine 373a-k in diethyl ether Method B yields the N -alkyl-4-methylbenzenesulfonamides 374a-k in moderate to excellent yields (4197\%).

### 1.2 Current synthesis of radical precursors

With a range of sulfonamides $\mathbf{3 7 4 a} \mathbf{- k}$ in hand, the next goal was to react these with 2-methyl-2-isobutyryl bromide 284, to prepare the range of substrates 369a-k suitable for investigation (Table 14). Initially triethylamine (1.0 eq.) was used followed by addition of the acid bromide 284, (see Method C). For the majority of reactions this method worked 369a-e,g-h, albeit with low yields for hindered and longer chain amines. However, for the hindered amines 369f,i-k only starting material $\mathbf{3 7 4}$ was recovered. By changing the conditions to use equimolar amounts of $n-\operatorname{BuLi}(1.6 \mathrm{M})$ Method $\mathbf{D}$, it was hoped to be able to force the formation of the hindered substrates $\mathbf{3 6 9 f}$,i-k. However, even under these conditions no products were detected. Therefore this synthesis was abandoned, and the rest of the work concentrated on the substrates 369a-e, g-h. For sulfonamides 278e, 374c-d, g-h traces of an olefinic product (tentatively assigned as 375 (Figure 19) based upon ${ }^{1} \mathrm{H}$ NMR and previous precedent), was also isolated (See Chapter Two).

## Chapter Three

### 2.0 Reaction of $N$-alkyl-4-methylbenzenesulfonamide with copper (I) bromide and TPA

As previously mentioned in Chapter 2, the reaction of substituted aryl sulfonamides when heated in refluxing toluene in the presence of copper (I) bromide and TPA 279 led predominately to the cyclised oxindole products. On the other hand changing the solvent to either DCM or (in some cases) THF led predominately to the rearranged amide. In light of these results an investigation was conducted on the effects of the alkyl $N$-substituent on the outcome of the reaction in DCM.. Previous work by Fullaway ${ }^{163}$ had shown that for the iso-butyl sulfonamide $\mathbf{3 6 9 g}$, using a slight excess of the copper (I) bromide/TPA complex in dichloromethane furnished the rearranged amide $\mathbf{3 7 0 g}$ in $26 \%$ yield and the cyclised product $\mathbf{3 7 1 g} / \mathbf{3 7 2 g}$ in $20 \%$. On repeating the reaction for the $N$-iso-butyl substrate $\mathbf{3 6 9 g}$ under similar conditions, there was greater selectivity towards the rearranged amide $\mathbf{3 7 0} \mathrm{g}$ in $76 \%$ yield and the cyclised product $\mathbf{3 7 1} \mathbf{g} / \mathbf{3 7 2 g}$ in $24 \%$ yield. The drawback with Fullaway's method, was that the conditions used in these experiments were not recorded, so it is uncertain as to what temperature was used and the length of time taken for complete conversion to products. Further work by Fullaway was done using the $N$-sec-butyl sulfonamide 369h, using a slight excess of the copper (I) bromide/TPA complex in dichloromethane. Again, there was greater selectivity over the rearranged amide versus the cyclised product 2:1 ratio. There was no indication concerning neither the temperature used nor the length of time taken for complete conversion to products.

### 2.1 Current work

Consequently, this work involved a re-investigation of these reactions. Heating the bromides $\mathbf{3 6 9} \mathbf{a}-\mathrm{h}$ in dichloromethane at $37^{\circ} \mathrm{C}$ for 18 hours furnished the expected products arising from rearrangement 370a-h and the two cyclised oxindoles

Table 15 The effects of dichloromethane on product distribution

The table for the $\mathrm{C}_{4}$ series 278a (parent, $\left.\mathrm{Ar}=\mathrm{Ph}, N-n-\mathrm{Bu}\right)$, 278e $(N-n-\mathrm{Bu}), \mathbf{3 6 9 g}(N-$ $i-\mathrm{Bu}), \mathbf{3 6 9 h}(N-s-\mathrm{Bu})$ shows the ratio of rearranged $\mathbf{3 7 0}$ to cyclised products $\mathbf{3 7 1 : 3 7 2}$ remains fairly constant (1.4:1 to $1.3: 1$ ). However when the chain length was

## Chapter Three

increased from $\mathrm{C}_{4}, \mathrm{C}_{5}, \mathrm{C}_{6}, \mathrm{C}_{12}$ (i.e. 369ce) the reaction becomes more selective for the rearranged product 370 (1.4:1, 2.5:1, 3.3:1 to 1:0). Full characterisation of the $N$ pentyl cyclised 371d/372d products was not possible due to the small amounts of isolated product (see Appendix 13). No cyclised material was isolated with the longest dodecyl substituted precursor 369e.

On the other hand, the smaller $N$-Et substitutent 369a did not fit this trend as the reaction was also selective for the rearranged product 370a. An authentic sample of 370a was prepared from the acid chloride 351, (see Chapter 2, Scheme 92 ) in order to unambiguously assign the structure of this compound.

The reasons for the trends are not clear. Presumably, the product distribution is determined from the relative rates of cyclisation versus reduction of the intermediate amidyl radical 335, (see Chapter 2, Scheme 87). The factors, which govern these rates, must be relatively complicated as in $n$ - $\mathrm{Bu}, i-\mathrm{Bu}, s$ - Bu series where there are slowly increasing steric hinderance at the nitrogen atom (but keeping the number of carbons constant) the ratios are very similar. Hence, steric effects alone cannot explain the trends. Reduction of the intermediate amidyl radicals can theoretically occur via two pathways; a) reduction by abstraction of an H -atom from the solvent, or b) reduction by intramolecular H-translocation followed by solvent (see $\mathbf{3 7 6} \rightarrow$ 377) as depicted in Scheme 112.

Scheme 112 Proposed mechanism for radical hydrogen translocation

## Chapter Three

There are two characteristic experiments, which might determine whether this intramolecular approach to reducing the amidyl radical intermediate is taking place. The first method would involve using a series of poor hydrogen donor solvents $(\mathrm{t}-\mathrm{BuOH}$, etc), and determining their effect on product outcome. The poor hydrogen donor solvents should retard the rate of intermolecular reduction but not that of intramolecular reduction and larger ratios of cyclisation should occur, since there would be poorly abstractable hydrogen atoms on the solvent. Another approach would be to use alternative groups at the C-5 position, to ensure that $1,5-\mathrm{H}$ abstraction could not take place. As a suggestion, the following compound 378 (Figure 20) could be used. In this case, the C-F bond is much stronger than the C-H and thus would be more difficult to break. The result being that a 1,5 -abstraction could not take place.

378

Figure 20 Structure of compound to block 1-5-H abstraction 378

Alternatively, the nature of the R group might affect the relative rates of oxindole formation. Presumably, with the small $N$-ethyl group, reduction via pathway (a) is relatively fast and/or cyclisation must be slow. Reduction via intramolecular 1,3-H abstraction is unlikely to occur. The smallest $N$-alkyl group capable of a $1,5-\mathrm{H}$ translocation is the $N$-Bu precursor 278e. As the $N$-alkyl group increases in size potentially more H -translocation pathways may be possible (1.6, -1.7 etc). This may explain why more selectivity towards reduction of the intermediate amidyl radical

## Chapter Three

(leading to rearrangement) is observed; alternatively the larger chain alkyl groups may retard the cyclisations.

### 2.2 Reactions in other solvents

In Chapter 2 it was shown that changing the solvent for the reaction from DCM to toluene led to a reversal of selectivity (i.e., in DCM the rearranged products normally predominated, but in toluene the cyclised compounds predominated). This was explained as DCM being a better H-donor towards the amidyl radicals An investigation of the reaction of three precursors $\mathbf{3 6 9 a}, 278 \mathrm{e}$ and $\mathbf{3 6 9 g}$ in toluene and in the ionic liquid $\mathrm{BMIM}_{4} \mathrm{BF}_{4}$, were conducted and compared with the results from DCM. A brief investigation of the effect of temperature on product outcome was also conducted (Table 16).

## Chapter Three

Scheme 113 General reaction scheme for $N$-alkyl substrates 369 with CuBr/TPA

| Entry |  | Solvent | Temp. | Conv. | Ratio 370:371/372 |
| :---: | :--- | :--- | :---: | :---: | :---: |

| VIII | $\mathbf{3 6 9 g}$ | Toluene | 110 | $\mathbf{7 3}$ | $\mathbf{0 . 6 : 1}$ |
| IX | $\mathbf{3 6 9 g}$ | IL | 50 | $\mathbf{9 4}$ | $\mathbf{0 . 5 : 1}$ |

Key: 369a = Ethyl, 278e $=n$-butyl, $\mathbf{3 6 9 g}=$ iso-butyl

Table 16 The effects of toluene and ionic liquid BMIM $^{\text {BF }} 4$ on product distribution.

As can be seen from Table 16 the expected reversal of selectivity is observed upon switching from DCM to toluene (e.g. 369a DCM 10:1 to toluene 0.8:1, 278e DCM 1.3:1 to toluene $0.4: 1, \mathbf{3 6 9}$ gCM 1.4:1 to toluene $0: 1$ ). The conversion however is less in toluene when compared to DCM presumably due to the relatively insoluble nature of the $\mathrm{CuBr} / \mathrm{TPA}$ in toluene compared to DCM .

## Chapter Three

Comparing the reactions in toluene at $50^{\circ} \mathrm{C}$ and $110^{\circ} \mathrm{C}$ the N -Et 369a undergoes the fastest reaction, followed by $N-n$-Bu 278e and $N-i-B u \mathbf{3 6 9 g}$. This would be expected on steric grounds. The low conversion of $N-i-\mathrm{Bu}$ ( $\mathbf{3 6 9 g}$ Entry VII) made determining the product ratio difficult from the crude NMR and so the result of this experiment should be treated with caution.

In toluene at $110^{\circ} \mathrm{C}$ the ratio for all three reactions II, IV and VI remain similar (0.7:1 to $0.6: 1$ ).This maybe due to the fact that the $\mathrm{CuBr} / \mathrm{TPA}$ complex is more soluble than in toluene but that the H -abstraction properties of both solvents might be similar.

This would indicate that the ionic liquid whilst only attaining similar selectivities for the rearranged amide/cyclised products shows that the ionic liquid has a higher rate of conversion. Further work would be required to determine with certainty this rate difference. Presumably, the ionic liquid can coordinate with the ligand complex and structure more favourably than that for toluene at the same temperature.

### 2.3 Other reactions

The following investigation concerning the reaction of the $N$-Et 369a, $N$-Pr derivative 369b and $N-n \mathrm{Bu}$ 281e in the ionic liquid $\mathrm{BMIM}_{\mathrm{BF}}^{4}$ at $50^{\circ} \mathrm{C}$ for 18 hs as depicted in Table 17.

## Chapter Three

Scheme 114 General reaction scheme for $N$-alkyl substrates 369 with $\mathbf{C u B r} / \mathrm{TPA}$

| Entry | Ratio 370:371/372 |
| :---: | :---: |
| $N-\operatorname{Et}(\mathbf{3 6 9 a})$ | $\mathbf{1 : 1}$ |
| $N-\operatorname{Pr}(\mathbf{3 6 9 b})$ | $\mathbf{0 . 5 : 1}$ |
| $N-\mathrm{nBu}(\mathbf{2 8 1 e})$ | $\mathbf{0 . 2 : 1}$ |

Table 17 The effects of the ionic liquid BMIM $\mathrm{BF}_{4}$ on product distribution.

In this case as the chain length increases the relative amounts of cyclised materials increases (in the case of the $N$-propyl, the cyclised products were isolated although full characterisation was not possible due to other by-products-see Appendix 14). This is opposite to the trend observed in DCM with increasing chain length. In order to investigate this further, similar experiments using $\mathrm{C}_{5}, \mathrm{C}_{6}$ and $\mathrm{C}_{12}$ alkyl groups should be conducted and compared to toluene at both $50^{\circ} \mathrm{C}$ and $110^{\circ} \mathrm{C}$. However, due to time constraints this was not achieved.

### 2.4 Effects of dichloromethane at room temperature on product distribution

 Having previously investigated the effects on substrates 369 (Table 15) in dichloromethane at $37^{\circ} \mathrm{C}$, an investigation of the following substrates $N$-ethyl 369a, $N$-hexyl 369d, $N$-dodecyl 369e, $N$ - $i$-butyl 369g, $N$ - $s$-butyl 369h at room temperature
## Chapter Three

(3 days) was conducted (Table 18). These results show that there is excellent selectivity towards the rearranged amide $\mathbf{3 7 0}$ compared to the cyclised regioisomeric oxindoles $\mathbf{3 7 1 / 3 7 2}$. It is uncertain as to whether this increased selectivity is due to the lower temperature used (room temperature) or the longer reaction time (3 days), or a combination of both. Results from Table 15 (DCM $37{ }^{\circ} \mathrm{C}$, 18 hrs ) are represented here as a comparison.

Key: 369a = ethyl, 369c = hexyl, 369d = dodecyl, $\mathbf{3 6 9} \mathbf{g}=$ iso-butyl, $\mathbf{3 6 9 h}=$ sec-butyl.

## Chapter Three

### 3.0 Synthesis of $N$-(hetero)aromatic radical precursors 380a-i

Having investigated the effects of simple alkyl chains attached to the nitrogen atom and their effects on product outcome, a further study was initiated whereby replacing the alkyl groups with benzyl derivatives such as (4-methyl benzyl, 4-methoxy benzyl and 2-trifluoromethyl benzyl) as well as aryl groups (phenyl, pyridylmethyl, quinuclidine, furan and thiophene) was investigated. In order to ascertain the effects of these substituents, the aryl acceptor group (tosyl) and initiation group ( $\mathrm{CMe}_{2} \mathrm{Br}$ ) were kept constant.

Figure 21 General structure for the (hetero)aryl derivatives 381

The approach to furnish these compounds was identical to that described in Section 3.1. Thus, $p$-tosyl chloride (1.0 eq.) 281e was treated with the amine of choice ( 1.0 eq.) 379a-i and triethylamine (1.0 eq.) in dichloromethane ( $\operatorname{Method} \mathbf{A}$ ), as depicted in Table 19 to furnished the $N$-(hetero)aryl-(4-methyl)-benzenesulfonamides 380a-i (Scheme 116).

## Chapter Three

Scheme 116 Synthesis of $N$-hetero(aromatic) substrates 380a-i

Table 19: Synthesis of $\boldsymbol{N}$-(hetero)aromatic-4-methylbenzenesulfonamides

The $N$-benzyl derivatives, (with the exception of the trifluoromethyl group 380c) gave poor yields (<33\%). Better yields were obtained for the heterocyclic substrates (furfuryl 380e in $75 \%$ yield and 2-thiophenemethyl $\mathbf{3 8 0 f}$ in $75 \%$ yield). No product could be isolated from the phenyl $\mathbf{3 8 0 g}$, pyrid-2-yl $\mathbf{3 8 0 h}$ and quinuclidine $\mathbf{3 8 0} \mathbf{i}$ substrates. Consequently, this work focussed only on the substrates 380a-f.

## Chapter Three

### 3.1 Synthesis of radical precursors

With the sulfonamides 380a-f in hand, the next goal was to react these with 2-methyl-2-isobutyryl bromide 284, to prepare the range of substrates 381a-f suitable for investigation (Scheme 117). This method involved triethylamine ( 1.0 eq.) followed by addition of the acid bromide 284 (Method B) as depicted in Table 20. For the majority of reactions this method worked 381a-e. However, for the thiophene derivative $\mathbf{3 8 1 f}$ only starting material $\mathbf{3 8 0 f}$ was re-isolated. Unlike the previous substrates, there was no presence of any elimination product in the crude NMR.

## Chapter Three

### 3.2 Attempted radical reactions of (hetero)aromatic sulfonamides 381

Motherwell ${ }^{151}$ has shown that benzylic sulfonamides can selectively furnish cyclic sulfonamides as depicted in Scheme 118. In all these reactions, a 1-7 addition onto the sulfonamide aromatic ring furnished the cyclic sulfonamides. In the following example, the pyridyl sulfonamide $\mathbf{2 5 7}$ furnished the desired cyclic product $\mathbf{2 5 8}$ (55\%) and the dihydropyridine 382. Switching to sulfur heterocyclics, the thiophene sulfonamide 259 led to the desired cyclised product 383 and two dihydroheteroaromatics $\mathbf{2 6 0}$ and $\mathbf{3 8 4}$ and $23 \%$ and $8 \%$ yield respectively. When the reaction was repeated for the quinoline sulfonamide $\mathbf{2 6 1}$ only the cyclised product $\mathbf{2 6 2}$ in 9\% yield was furnished.

Scheme 118 Motherwell radical cyclisation onto heteroaromatics

## Chapter Three

Based on these observations, it may be possible for the radical $\mathbf{3 8 5}$ produced from N -4-methoxybenzyl substrate 381b (Scheme 119), to undergo two competitive cyclisation pathways. (A) Radical cyclisation onto the benzylic group via a 1,6addition to furnish analogous cyclic sulfonamide $\mathbf{3 8 6}$ as above. (B) Addition into the ipso position of the sulfonamide via a 1,5- addition (as observed in our previous studies) to lead to the rearranged amide 387. It should be noted that a previous reaction by Wongtap ${ }^{156}$ using the substrate 381a furnished the rearranged amide analogous to 387 .

Scheme 119 Proposed radical mechanism for the substrate 387

The first experiment involved treating the benzyl bromide 381b with $\mathrm{CuBr} / \mathrm{TPA}$ in tetrahydrofuran at $50^{\circ} \mathrm{C}$ for 24 h . Unfortunately, the crude NMR showed several products. None of these products could be unambiguously identified and no evidence of either cyclised products $\mathbf{3 8 6}$ or rearranged amide $\mathbf{3 8 7}$ could be detected. In light of this result, and due to time constraints additional investigations for the benzylic precursors 381a,c were cancelled, and instead analysis of the heterocyclic aromatic derivatives, (e.g. the N -furan derivative 381e) was performed.

Zard ${ }^{245}$ has recently shown that a suitably substituted furan xanthate $\mathbf{3 8 8}$ can undergo ipso-type radical cyclisation to furnish spirocyclised products (e.g. 392). (Scheme

## Chapter Three

120). The xanthate 388 was treated with DLP (dilauroyl peroxide) to give the acyl radical intermediate $\mathbf{3 8 9}$, which underwent an ipso-type cyclisation leading to the spirocyclised radical intermediate $\mathbf{3 9 0}$ followed by oxidation to the cation $\mathbf{3 9 1}$ which is quenched by the solvent to give the spirocyclised product 392.

Scheme 120 Zard's synthetic approach to spirocyclised products using furan xanthates

It may be possible for the present substrate 381e to undergo a similar type of cyclisation to furnish spirocyclised products as well as the radical rearrangement 395 and oxindole formation that have been observed in related studies to this work, alternatively, the substrate may undergo other cyclisations as shown in Scheme 121.

Scheme 121 Proposed radical mechanisms for the substrate 381e

## Chapter Three

However, on heating the bromide 381e in tetrahydrofuran at $50^{\circ} \mathrm{C}$ for 24 hours the crude NMR and the TLC indicated several products as before with 381b. None of these could be properly isolated and purified and therefore they were not exhaustively analysed. Consequently, due to both 381b and 381e that gave complicated mixtures, this resulted in cessation of further investigations into this class of substrates.

### 4.0 Conclusion for Chapter Three

The starting sulfonamides were treated with 2 -bromo-2-isobutyl bromide and triethylamine to yield the radical precursors. The $N$-butyl group gave the best yield (70\%). The yields decreased from $N$-butyl to $N$-docecyl. With more hindered substrates the reaction failed presumably due to steric hinderance. The iso-butyl and sec-butyl substrates gave average yields of $48 \%$ and $56 \%$ respectively. Again, steric hindrance was responsible for the lower yield.

As with Chapter 2, in the copper mediated radical reactions there was a similar trend in selectivity towards the rearranged amide $\mathbf{3 7 0}$ (in dichloromethane), and regioisomeric oxindoles $\mathbf{3 7 1 : 3 7 2}$ (in toluene or ionic liquid $\mathrm{BMIM}_{\mathrm{BF}}^{4}$ ). The initial study on a range of substrates $\mathbf{3 6 9}$ in dichloromethane at $37{ }^{\circ} \mathrm{C}$, showed marked selectivity towards the rearranged amide $\mathbf{3 7 0}$ (compared to the parent compound 278a). It was shown that as the $N$-alkyl chain increases, the selectivity towards the rearranged amide increases also, with the exception of 369a which showed high selectivity. The reasons for this trend are reduction of the amidyl radical which leads to amide $\mathbf{3 7 0}$ whereas cyclisation leads to $\mathbf{3 7 1 / 3 7 2}$. The reduction of the amidyl radical could arise from two possible pathways, (a) hydrogen abstraction of the H atom from the solvent or (b) from an intramolecular H-translocation. The efficiency of the latter would be expected to increase with increasing chain length (as

## Chapter Three

observed). The selectivity observed with the $N$-Et group would indicate that there is a rapid reduction of the amidyl radical from the solvent (DCM), relative to cyclisation. Dichloromethane at room temperature has a greater selectivity towards the rearranged amide 370, (but keeping the trend the same) compared to dichloromethane at $37^{\circ} \mathrm{C}$. The nature of the $N$-alkyl group has two possible rules. It is known that it can affect rates of cyclisations of both carbon and nitrogen based radicals and also provides pathways for intramolecular reduction. In 5-exo cyclisation of $\alpha$-amide radicals, small nitrogen substituents cause a relatively slow rate of cyclisation due to unfavorable rotamer ratios. However, in this case (amidyl radicals) cyclisation has been shown to be retarded by bulky substituents. ${ }^{158}$ Thus it is unclear why the relative rate of cyclisation for the $N$-ethyl substituent is slow. This suggests that it is the rate of reduction which is fast (presumably intermolecular reduction).

In a another set of reactions, (this time using toluene at both $50^{\circ} \mathrm{C}$ and refluxing temperature $\left(110{ }^{\circ} \mathrm{C}\right)$ and ionic liquid at $\left.50^{\circ} \mathrm{C}\right)$ of three substrates, $N$-Et 369a, $N-n-$ Bu 369d and $N-i$-Bu 369i the expected reversal of selectivity leading to the cyclised products 371:372 was observed. As in Chapter Two, the selectivity towards the cyclised products was evident. The explanation for this is that toluene is a poor hydrogen donor compared to DCM, and that the major path must be through addition onto the aromatic ring via the amidyl radical intermediate 335. Interesting, when the ionic liquid-BMIM $\mathrm{BF}_{4}$ was compared to toluene at $50^{\circ} \mathrm{C}$, there was a greater rate of conversion presumably due to increased solubility of $\mathrm{CuBr} / \mathrm{TPA}$, but a similar ratio of products were observed due to similar H -donor ability to toluene. With the ionic liquid reactions, there was a reversal of selectivity toward cyclisation $\left(\mathrm{C}_{2}-\mathrm{C}_{5}\right)$. The reason for this remains unclear. Further investigation by replacing the alkyl group

## Chapter Three

with an aryl or heteroaromatic group was conducted. It was not possible to obtain any meaningful data however.

## CHAPTER FOUR

## REACTIONS OF $N$-ETHYL- $N$ -

## TRICHLOROACETYL-4-

## METHYLBENZENESULFONAMIDE

AND HALO-AMIDES WITH CuX/TPA

## Chapter Four

### 1.0 Introduction

Having investigated the effects of N -butyl-(substituted)-benzenesulfonamides 278, N -alkyl-4-methylbenzenesulfonamides $\mathbf{3 6 9}$ and N -aryl-4-methylbenzenesulfonamides 381 upon product outcome, a series of radical initiators were investigated as depicted in Figure 22.

Figure 22 Structure of arylsulfonamide using various radical initiators
All previous investigations have been conducted using unactivated radical initiators, as described in both Chapter 2 and 3. Due to time constraints, a thorough investigation of all initiators was not possible. Therefore, substrates were used based on the previous work by the Clark group ${ }^{154}$ as described in Chaper 1 section 3.5 page 81. In this case, the radical precursor 275 when treated with copper (I) chloride and TPA complex lead to the rearranged amide 277 as depicted in Scheme 122. Although, this was only determined through the crude proton NMR, as it was not possible to obtain the pure product.

Scheme 122 Clark's rearrangement reaction using arylsulfonamide 275

### 1.1 Investigation of the trichloroacetamide substrate 396

A brief investigation of the effects of varying the initiator portion of the molecule on one of the previously investigated derivative 369a was undertaken as depicted in

## Chapter Four

Figure 22. In this case, the unactivated bromide initiator $\left(\mathrm{CMe}_{2} \mathrm{Br}\right)$ was substituted for an activated $\left(\mathrm{CCl}_{3}\right)$ initiator 396.

369a

396

Figure 23 The structures of the radical precursors 369a and 396

The precursor 396 was prepared from commercially pure 369a (1.0 eq.) with trichloroacetyl chloride 397 (1.0 eq.) and $n$-butyllithium ( 1.0 eq.) in excellent yields in 84\% yield as depicted in Scheme 123.

## Scheme 123 Synthesis of trichloroacetamide 396

It should be possible to observe a similar reaction with the substrate $\mathbf{3 9 6}$ to furnish the rearranged amide 398 as outlined below.

Scheme 124 General reaction scheme for substrate 396 with $\mathbf{C u B r} /$ TPA

## Chapter Four

### 1.2 Radical reaction of the trichloroacetamide 396

The next step was to react this under identical conditions to that in Chapter ThreeTable 15. The trichloroacetamide $\mathbf{3 9 6}$ was heated in dichloromethane at $37^{\circ} \mathrm{C}$ for 18 hours. The reaction was carefully monitored by TLC, which showed several products which included unreacted starting material 396. In addition it was possible to identify the expected rearranged amide 398, and the cyclised product 399 (see Scheme 125) in a ratio of [1.0:1.6] 398:399 (based upon crude NMR spectra). Based on the analogous reaction with the bromide 369a it was observed that the use of the trichloroacetamide 396 as a substrate was less efficient in mediating the rearranged amide (compared to the bromide where there was excellent selectivity for $\mathbf{3 7 0 a}$, e.g. 10:1 versus 1.6:1).

370a

371

372

Figure 24 Structures of the $N$-ethyl cyclised and rearranged products

Scheme 125 Radical reaction of trichloroacetamide with $\mathbf{C u B r} / T P A$ An analogous reaction by Wongtap ${ }^{156}$ with N -butyl trichloroacetamide furnished the rearranged amide in excellent yield (100\%), but surprisingly as shown in Chapter One-Section 3.5, the $N$-allyl derivatives 275 furnished only a low yield (10\%), although only tentatively assigned by NMR.

## Chapter Four

### 2.0 Synthesis of oxindoles from halo-amides

Oxindoles have been prepared via radical cyclisation onto aromatic rings. An example is Nishio's radical cyclisation ${ }^{178}$ (Scheme 126) whereby the bromide $\mathbf{4 0 0}$ when treated with tributyltin hydride and AIBN underwent radical cyclisation into the aromatic ring to give the radical intermediate 401, followed by re-aromatisation to furnish the oxindole 402. Another related reaction is Storey's ${ }^{59}$ (Scheme 127) tributyltin hydride radical cyclisation of ortho halo anilides derivatives (not shown) to furnish oxindoles (eg. 405). In this case 1,5-H translocation of the aryl radical $\mathbf{4 0 3}$ to $\mathbf{4 0 4}$ followed by addition into the aromatic and oxidation furnishes the observed product.

Scheme 126 Nishio's radical approach to oxindoles

## Scheme 127 Storey's radical approach to oxindoles

The following investigation to determine if similar cyclisations of haloacetamides (eg. 278e, 406-409) could be mediated by copper-TPA complex was undertaken. Thus it was postulated that generating the radical from the precursors 406-408 using either CuBr or CuCl and TPA would lead to a radical cyclisation into the aromatic ring followed by oxidation via the copper (II) halide complex to give the cyclised oxindole products 409-411 (Scheme 128).

## Chapter Four

Scheme 128 Proposed mechanism for oxindole synthesis using CuBr/TPA
Cyclisation precursors were prepared whereby the initiating radical would be produced from functionality which contained the tertiary bromide 341, a dichloroacetamide 406, a trichloroacetamide 407 and a primary bromide 408 (Figure 24).

$281 e$

406

407

408

Figure 25 The functionized initiators 341 and 406-408

### 2.1 Synthesis of precursors 278e, 406-408

The dichloroacetamide 406 was prepared by reacting the amine ( 1.0 eq.) 340 with dichloroacetyl chloride (1.0 eq.) 412 with butyllithium (1.0 eq.) as a base. NMR spectroscopic analysis showed the desired precursor 406 was produced (in $46 \%$ yield) but also the de-alkylated amide 413 was obtained and this was inseparable by chromatography from 406 (Scheme 129).

## Chapter Four

Scheme 129 Synthetic approach to dichloro precursor 406
The trichloroacetamide ( 1.0 eq.) 407 was prepared successfully by simply reacting the amine (1.0 eq.) 340 with trichloroacetyl chloride (1.0 eq.) 397 and butyllithium (1.0 eq.) in excellent yield ( $82 \%$ ). The primary bromide 408 was prepared by reacting the amine $\mathbf{3 4 0}$ with acetyl bromide and triethylamine (1.0 eq).

### 2.2 Reactions of radical precursors 281e, 409-411

The precursor 281e was heated in refluxing toluene with one equivalent of CuBr and TPA for 24 hours. The crude NMR showed one compound, which was identified as the oxindole 333 upon purification ( $98 \%$ ) as depicted in Scheme 130. Oxindole $\mathbf{3 3 3}$ may be formed via the desired radical cyclisation mechanism outlined earlier (see Scheme 87, page 110) or it could be produced by a similar mechanism to the FriedelCrafts alkylation (with the CuBr acting as a Lewis acid mediator). The radical process would likely be catalytic as the copper (II) bromide formed in the initiation event would oxidise the intermediate cyclohexadienyl radical 414 to the aromatic oxindole and regenerate the copper (I) bromide. On the other hand, Friedel-Crafts alkylation reactions are not generally catalytic and stoichiometric amounts of lewis acid reagent are required.

## Chapter Four

Scheme 130 Copper-mediated radical cyclisation of precursor 341
It was impossible to distinguish between these mechanisms because one equivalent of $\mathrm{CuBr} / \mathrm{TPA}$ was used. In light of this result, and in order to determine whether a stoichiometric amount of copper bromide was required, the reaction was repeated using $30 \% \mathrm{CuBr} / \mathrm{TPA}$ under otherwise identical conditions as before. Although NMR analysis of the crude reaction confirmed that the oxindole $\mathbf{3 3 3}$ was present, there were a number of other by-products formed. The oxindole 333 was formed in only $16 \%$ isolated yield. In this case, because of the low yield, it was still unclear whether a catalytic radical process was involved, or a stoichiometric Friedel-Craft cyclisationalthough it may suggest the latter.

### 2.3 Additional reactions

The next step was to investigate the reaction of the trichloroacetamide 407 to determine if this too would undergo a similar reaction. Thus 407 was heated in refluxing toluene for 24 hours with CuCl and TPA and the reaction was monitored by TLC. The crude NMR showed unreacted starting material and oxindole 415 (Scheme 131) (tentatively assigned from the $\mathrm{NCH}_{2}$ group and by comparison of spectroscopic details of the related oxindole 333. As with the sulfonamide analogue 396 there were a number of by-products.

## Chapter Four

Scheme 131 Copper-mediated radical cyclisation of trichloroacetamide 396
Finally, an investigation of the primary bromide precursor 408 was performed to determine if cyclisation could occur. The primary halide is likely to be much more difficult to cleave homolytically due to a stronger $\mathrm{C}-\mathrm{Br}$ bond than the tertiary bromide 341. In fact, previous work in the group had shown that generating radicals from primary bromides often did not succeeed. The halide was heated in refluxing toluene for 48 hours with a stoichiometric amount of CuBr and TPA. This time, the crude NMR showed unreacted starting material.

### 3.0 Conclusion for Chapter Four

Firstly changing the initiating group from tertiary bromide $\mathbf{2 8 4}$ to trichloroacetyl $\mathbf{3 9 7}$ in the $\mathrm{CuCl} / \mathrm{TPA}$ mediated rearrangement reactions was found to be detrimental to the rate, yield and substituents of the process. This highlights the limitation of the rearrangement reactions described.

Secondly it has been shown that it is possible to prepare oxindoles directly from dimethylbromoacetylamides by heating with $\mathrm{CuBr} / \mathrm{TPA}$. Mechanistically this reaction might proceed by a Friedel-Crafts alkylation mediated by the copper lewis acid or a radical addition/oxidation process. The low yield produced with sub-stoichiometric amounts of reagent tentatively indicated the former process. As with the rearrangement reactions of sulfonamides, changing the group from tertiary bromide 284 to trichloroacetyl 397 was detrimental to the overall yield of the process. Attempted cyclisation of the bromoacetamide 408 failed, either because the $\mathrm{C}-\mathrm{Br}$

## Chapter Four

bond could not be broken (either homolytically or heterolytically) or due to relatively slow cyclisation of primary bromides relative to tertiary bromides $\mathbf{2 8 4}$ (due to absence of the gem methyl effect).

### 4.0 Future work

The following recommendation may help improve the oxindole forming reaction and thus improve yields..

- The use of a series of different ligands should be tested. In these studies only the copper (I) bromide (chloride) and TPA were used. Varying the ligand may effect solubility, reactivity and mechanistic properties.

Experimental

## CHAPTER FIVE

## EXPERIMENTAL

## Experimental

### 1.0 General

${ }^{1} \mathrm{H}$ NMR spectra were recorded at 300,400 and 500 MHz on the Bruker DPX300, DPX400 and DPX500 spectrometer respectively, and are in $\mathrm{CDCl}_{3}$ unless otherwise stated. All chemical shifts ( $\delta$ ) are quoted in parts per million ( ppm ) with deuterated chloroform $\left(\mathrm{CDCl}_{3}, \delta_{\mathrm{H}}=7.26 \mathrm{ppm}\right)$ in tetramethylsilane $\left(\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{4},(\mathrm{TMS}), \delta_{\mathrm{H}}=0.00\right)$ as internal reference unless otherwise stated. Coupling constants ( $J$ ) were measured in Hz. ${ }^{13} \mathrm{C}$ NMR (DEPT) were recorded at $75.5,100.6$ and 125.8 MHz on the Bruker DPX300, DPX400, and DPX500 spectrometer respectively, with $\mathrm{CDCl}_{3}$ in TMS as internal reference unless otherwise stated. Infrared spectra were recorded on a Perkin-Elmer 1720X fourier-transform infrared spectrometer (Golden-Gate method). Mass Spectra were recorded using a Micromass Autospec. Mass Spectra were recorded using EI (Electron Impact), CI (Chemical Ionisation), or LSIMS (Liquid Secondary Ion Mass Spectrometry)-FAB (Fast Atom Bombardment) at both low and high resolution. LSIMS were carried out in a PEG300 in 3-NBA matrix. Melting points were recorded on a Gallenkamp melting point apparatus and are uncorrected. Analytical TLC were performed using Merck aluminium sheet silica gel $60 \mathrm{~F}_{254}$. Column chromatography was performed with Fluorochem ${ }^{\circledR}$ silica gel 40-63 60A. Visualizations were performed using ultraviolet radiation at 254 nm , acidic polymolybdonate or basic potassium permanganate, unless otherwise stated. All chemicals were commercially available from Aldrich and used without further purification. All solvents were used without further purification. All organic reactions were performed under nitrogen atmosphere unless otherwise stated. All organic products were dried over either anhydrous magnesium sulfate or anhydrous sodium sulfate. Nomenclature for the compounds was obtained from Beilstein Autonom software programmes. All elemental analysis was obtained

## Experimental

from Warwick Analytical Service or Medac Elemental Analysis. The following compounds 283b-j, 374b-j,l and 379a-b,d-f are commercially available in milligram quantanties only.

## Abbreviations:

### 1.1 General synthesis of $\boldsymbol{N}$-butyl-(substituted)-arylsulfonamides

### 1.1.1 Method A

To a stirred solution of the arylsulfonyl chloride 281 (1.2 eq.) in dichloromethane (DCM) ( 50 mL ) was added $n$-butylamine 282 (1.0 eq.) and triethylamine (TEA) (1.36 eq.). The solution was stirred at $0{ }^{\circ} \mathrm{C}$ (ice bath) for four hours unless otherwise stated. The reaction was quenched with distilled water $(50 \mathrm{~mL})$ and the product extracted with DCM or ether ( $3 \times 50 \mathrm{~mL}$ ). The combined organic extracts were dried over anhydrous magnesium sulfate and the solvent removed in vacuo to yield the crude arylsulfonamide 283. Purification was by recrystallization (diethyl ether/hexane) or flash chromatography (petroleum ether/ethyl acetate).

## Experimental

### 1.1.2 Method B

As above but arylsulfonyl chloride (1.0 eq.) $\mathbf{2 8 1}$ and amine (3.0 eq.) $\mathbf{2 8 2}$ were reacted in diethyl ether. No purification was required with this method.
$N$-Butyl-benzenesulfonamide 283a ${ }^{168}$

Commercially available from Aldridge [3622-84-2]. Method B: Furnished N-butylbenzenesulfonamide 283a as a clear oil (27.60g, 99\%). IR (neat) $v_{\text {max }}$ : 3274, 2958, 2869, $1316,1155,795,687 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.92-7.89(\mathrm{~d}, J=7.0,2 \mathrm{H}$, ArCH), 7.58-7.48 (m, 3H, ArCH), 5.41 (bs, 1H, NH), 2.92 (t, $J=7.0,2 H, C_{2}$ ), 1.461.39 (quin., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.33-1.23 (sxt., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 0.80 (t, $J=7.0,3 \mathrm{H}$, $\mathrm{CH}_{3}$ ). ${ }^{13} \mathrm{C}$ NMR ( $100.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $139.9\left(\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}\right.$ ) , 132.5 (d, ArCH ), 129.1 ( 2 x d, ArCH$), 127.0(2 \mathrm{x}$ d, ArCH$), 42.9\left(\mathbf{t}, \mathbf{C H}_{2}\right), 31.4\left(\mathbf{t}, \mathbf{C H}_{2}\right), 20.0\left(\mathbf{t}, \mathbf{C H}_{2}\right), 13.5(\mathbf{q}$, $\mathrm{CH}_{3}$ ). LRMS (LSIMS-FAB ${ }^{+}$) m/z: $214\left(\mathrm{MH}^{+}=100 \%\right), 154$ (57), 136 (40). Found: C, 41.5; H, 3.8; N, 4.0\%.

### 2.0 General synthesis of N -alkyl-4-methyl-benzenesulfonamides

### 2.1 Method A

To a stirred solution of 4-methyl-benzenesulfonyl chloride 281 (1.2 eq.) in dichloromethane (DCM) ( 50 mL ) was added the alkylamine 373 ( 1.0 eq.) and triethylamine (TEA) (1.36 eq.). The solution was stirred at $0{ }^{\circ} \mathrm{C}$ (ice bath) for four hours unless otherwise stated. The reaction was quenched with distilled water $(50 \mathrm{~mL})$ and the product extracted with DCM or ether ( $3 \times 50 \mathrm{~mL}$ ). The combined organic extracts were dried over anhydrous magnesium sulfate and the solvent removed in vacuo to yield the crude arylsulfonamide 374. Purification was by recrystallization (diethyl ether/hexane) or flash chromatography (petroleum ether/ethyl acetate).

### 2.2 Method B

As above but 4-methylbenzenesulfonyl chloride $\mathbf{2 8 1}$ and alkylamine $\mathbf{3 7 3}$ (3.0 eq.) were reacted in diethylether. No purification was required with this method.

## Experimental

## $N$-Ethyl-4-methyl-benzenesulfonamide $374 \mathbf{a}^{228}$

Commercially available from Aldrich [80-39-7]. Method B: Furnished $N$-ethyl-4-methylbenzenesulfonamide 374a as an hydroscopic white crystallized solid (4.78g, 84\%). mp 67.9-68.9 ${ }^{\circ} \mathrm{C}$. IR (neat) $v_{\text {max }}: 3268,2978,2876,2361,1322,1157,814 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (300MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 7.79(\mathrm{~d}, J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 7.32(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 5.11$ (app. t, $J=5.0,1 \mathrm{H}, \mathrm{NH}$ ), 2.97 (quin., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.08(\mathrm{t}, J$ $=7.0,3 \mathrm{H}, \mathrm{CH}_{3}$ ). ${ }^{13} \mathrm{C}$ NMR ( $75.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 143.1 ( $\mathbf{s}, \mathbf{C}-\mathrm{Me}$ ), 136.7 ( $\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}-$ ), $129.4(2 \times \mathrm{d}, \mathrm{ArCH}), 126.9(2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}), 37.3\left(\mathbf{t}, \mathbf{C H}_{2}\right), 21.3\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 14.7(\mathbf{q}$, $\mathrm{CH}_{3}$ ). LRMS ( $\mathrm{EI}^{+}$) $m / z: 199\left(\mathrm{M}^{+}=20 \%\right), 184$ (90), 155 (100). HRMS (LSIMS-FAB ${ }^{+}$) $m / z$ : calcd for $\mathrm{C}_{9} \mathrm{H}_{14} \mathrm{NO}_{2} \mathrm{~S}\left(\mathrm{MH}^{+}\right)$, 200.0745; found, 200.0742. Elemental Analysis (WAS): Calcd. for $\mathrm{C}_{9} \mathrm{H}_{13} \mathrm{NO}_{2} \mathrm{~S}: \mathrm{C}, 54.2 ; \mathrm{H}, 6.6 ; \mathrm{N}, 7.0$. Found: C, $54.3 ; \mathrm{H}, 6.5 ; \mathrm{N}, 7.0 \%$. $N$-Propyl-4-methyl-benzenesulfonamide 374b ${ }^{229}$

Commercially available from Interchim [1133-12-6]. Method B; Furnished N-propyl-4-methyl-benzenesulfonamide 374b as a yellow viscous solid (5.43g, 81\%). mp $27-28^{\circ} \mathrm{C}$. IR (neat) $v_{\text {max }}: 3275,2968,2875,1315,1156$ and $814 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (300MHz, $\mathrm{CDCl}_{3}$, $\delta$ ): 7.66 (d, $J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 7.17$ (d, $J=8.0,2 \mathrm{H}, \operatorname{ArCH}$ ), 5.52 (app.t, $J=5.0,1 \mathrm{H}$, $\mathrm{NH}), 2.75$ (t, $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 2.28 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{ArCH}$ ), 1.40-1.31 ( $\mathrm{sxt} ., J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.72\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR (100MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 143.0(\mathbf{s}, \mathbf{C}-\mathrm{Me}), 136.8(\mathbf{s}, \mathbf{C}-$ $\mathrm{SO}_{2^{-}}$), 129.4 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 126.9 ( $2 \mathrm{x} \mathbf{d}, \mathrm{ArCH}$ ), $44.7\left(\mathbf{t}, \mathbf{C H}_{2}\right)$, $22.6\left(\mathbf{t}, \mathbf{C H}_{2}\right)$, $21.1(\mathbf{q}$,

## Experimental

$\left.\left.\mathrm{ArCH}_{3}\right), 10.9\left(\mathbf{q}, \mathbf{C H}_{3}\right) . \operatorname{LRMS}(\mathrm{CI}) m / z: 214 \mathrm{MH}^{+}=22 \%\right), 196$ (35), 184 (67), 155 (90), 139 (15). HRMS (CI) calcd for $\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S} ; 213.0823$, found 213.0817. Elemental Analysis (WAS): Calcd. for $\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S} ; \mathrm{C}, 56.1 ; \mathrm{H}, 7.1 ; \mathrm{N}, 6.6$. Found: C, 55.9; H, 7.1; N, 6.4\%.

## 4-Methyl-N-pentyl-benzenesulfonamide 374d

Commercially available from Aurora Fine Chemicals [106011-68-1]. Method B: Furnished 4-methyl-N-pentyl-benzenesulfonamide 374d as a colourless oil (5.80g, 92\%). IR (neat) $v_{\text {max }}: 3276,2929,1322,1155,813,659 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right)$ : 7.74 (d.t, $J=8.0$ and $2.0,2 \mathrm{H}, \operatorname{ArCH}), 7.30(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 4.35(\mathrm{t}, J=6.0,1 \mathrm{H}$, NH), 2.92 (q, $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $2.43\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.49-1.41$ (app. quin., $J=7.0,2 \mathrm{H}$, $\mathrm{CH}_{2}$ ), 1.27-1.21(m, 4H, CH2), $0.84\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$, ס): 143.3 (s, C-Me), 137.0 ( $\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}-$ ), 129.7 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 127.1 ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), 43.2 $\left(\mathbf{t}, \mathbf{C H}_{2}\right), 29.2\left(\mathbf{t}, \mathbf{C H}_{2}\right), 28.7\left(\mathbf{t}, \mathbf{C H}_{2}\right), 22.1\left(\mathbf{t}, \mathbf{C H}_{2}\right), 21.5\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 14.3\left(\mathbf{q}, \mathbf{C H}_{3}\right)$. ## N-Adamantan-1-yl-4-methylbenzenesulfonamide 3741 ${ }^{238}$

Commercially available from Ambinter [56432-99-6]. Method A: Recrystallisation furnished $N$-adamantan-1-yl-4-methylbenzene sulfonamide 3741 as a white floury solid (6.10g, 76\%); IR (neat) $v_{\max }: 3228,2971,2844,1328,1114{ }^{\text {and }} 665 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR (400MHz, $\left.\mathrm{CDCl}_{3}, \delta\right) 7.77$ (d.t $J=8.0$ and $\left.2.0,2 \mathrm{H}, \mathrm{ArCH}\right), 7.27(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH})$,

## Experimental

4.45 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{NH}$ ), $2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.00(\mathrm{bs}, 3 \mathrm{H}, \mathrm{CH}), 1.78$ (app. s, 6H, CH2), 1.57 (m, 6H, CH2). ${ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 142.7$ (s, C-Me), 141.1 (s, C-SO $\mathbf{C l}_{2}$ ), 129.4 ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), 126.9 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), $55.1(\mathbf{s}, \mathbf{C}-\mathrm{NH}-), 43.1\left(3 \mathrm{xt}, \mathbf{C H}_{2}\right), 35.9(3 \times \mathbf{t}$, $\left.\mathbf{C H}_{2}\right), 29.5(3 \times \mathrm{d}, \mathbf{C H}), 21.5(\mathbf{q}, \mathrm{ArCH})$. LRMS (LSIMS-FAB $\left.{ }^{+}\right) \mathrm{m} / \mathrm{z}: 306\left(\mathrm{MH}^{+}=46 \%\right)$, 154 (32), 135 (100). HRMS (LSIMS-FAB ${ }^{+}$) $m / z$ : calcd for $\mathrm{C}_{17} \mathrm{H}_{23} \mathrm{NO}_{2} \mathrm{~S}$; 304.1371, found 304.1370. Elemental Analysis (WAS): Calcd for C, 66.8, H, 7.6, N, 4.6; $\mathrm{C}_{17} \mathrm{H}_{23} \mathrm{NO}_{2} \mathrm{~S}$, Found: C, 66.7, H, 7.5, N, 4.6\%.

### 3.0 General synthesis of N -alkyl-(4-methyl)-benzenesulfonamides

### 3.1 Method A

To a stirred solution of 4-methylbenzenesulfonyl chloride 281e (1.2 eq.) in dichloromethane (DCM) ( 50 mL ) was added the amine 379 ( 1.0 eq.) and triethylamine (TEA) (1.36 eq.). The solution was stirred at $0{ }^{\circ} \mathrm{C}$ (ice bath) for four hours unless otherwise stated. The reaction was quenched with distilled water ( 50 mL ) and the product extracted with DCM or ether ( $3 \times 50 \mathrm{~mL}$ ). The combined organic extracts were dried over anhydrous magnesium sulfate and the solvent removed in vacuo to yield the crude arylsulfonamide 380. Purification was by recrystallization (diethyl ether/hexane) or flash chromatography (petroleum ether/ethyl acetate).

### 5.3.2 Method B

As above but 4-methyl-benzenesulfonyl chloride (1.0 eq.) 281e and arylamine ( 3.0 eq.) 379 were reacted in diethylether. No purification was required with this method.

## Experimental

4-Methyl- $N$-(4-methylbenzyl)-benzenesulfonamide 380a ${ }^{239}$

Commercially available from Ambinter [10504-92-4]. Method A: Recrystallization furnished 4-methyl-N-(4-methylbenzyl)-benzenesulfonamide 380a as a yellow crystallised solid ( $1.59 \mathrm{~g}, 22 \%$ ). mp $80.5-81.5^{\circ} \mathrm{C}$. IR (neat) $v_{\text {max }}$ : 3270, 2916, 1324, 1152, 843, $798,741,657 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (400MHz; $\mathrm{CDCl}_{3}, \delta$ ): 7.76 (d. $J=8.0,2 \mathrm{H}, \mathrm{ArCH}$ ), 7.27 (d. $J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 7.10(\mathrm{~d}, J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 7.08(\mathrm{~m}, 2 \mathrm{H}, \operatorname{ArCH}), 5.50(\mathrm{t}, J$ $=6.0,1 \mathrm{H}, \mathrm{NH}), 4.06\left(\mathrm{~d}, J=6.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.43\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR (100MHz, $\mathrm{CDCl}_{3}, \delta$ ): 143.3 (s, $\mathbf{C - M e}$ ), 137.3 (s, $\mathbf{C - C H} \mathbf{2}_{-}$), 137.0 (s, $\mathbf{C -} \mathrm{SO}_{2}-$ ), 133.6 (s, C-Me), 129.7 ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), 129.3 ( $2 \times \mathrm{d}$ d, ArCH ), 127.9 ( $2 \times \mathrm{dd}, \mathrm{ArCH}$ ), 127.2 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), $46.9\left(\mathbf{t}, \mathrm{CH}_{2}\right), 21.5\left(\mathbf{q}, \mathrm{ArCH}_{2}\right), 21.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right)$. LRMS (LSIMS-FAB ${ }^{+}$) $m / z: 276\left(\mathrm{MH}^{+}=68 \%\right), 184(26), 154(100), 137(70)$. ## 4-Methyl- $N$-(2-thienylmethyl)-benzenesulfonamide $380 f$

Commercially available from Ambinter [545358-50-7]. Method A: Recrystallisation furnished 4-Methyl-N-(2-thienylmethyl)-benzenesulfonamide $\mathbf{3 8 0 f}$ as golden yellow crystallised solid (4.95g, 75\%). IR (neat) $v_{\max }: 3286,2977,2862,1320,1117,613 \mathrm{~cm}^{-1}$. ${ }^{1} \mathrm{H}$ NMR (400MHz; $\left.\mathrm{CDCl}_{3}, \delta\right): 7.73(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 7.28(\mathrm{~d}, J=8.0,2 \mathrm{H}$, ArCH), 7.16 (app. d., $J=1.0,1 \mathrm{H}, \mathrm{ArCH}$ ), 6.85 (app. quin., $J=3.0,2 \mathrm{H}, \mathrm{ArCH}$ ), 5.00 (bs, $1 \mathrm{H}, \mathrm{NH}$ ), $4.31\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right) .{ }^{13} \mathrm{C} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right)$ : 143.6 (s, C-Me), 139.0 ( $\mathbf{s}, \mathbf{C}$-thiophene), 136.8 ( $\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}-$ ), 129.8 ( $2 \times \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 127.8 $(\mathbf{d}, \mathbf{C H}), 126.9(\mathbf{d}, \mathbf{C H}), 126.5(\mathbf{d}, \mathbf{C H}), 125.8(2 \times \mathrm{d}, \mathrm{ArCH}), 42.1\left(\mathbf{t}, \mathrm{CH}_{2}\right), 21.6(\mathbf{q}$, $\left.\mathrm{ArCH}_{3}\right) . \operatorname{LRMS}\left(\mathrm{LSIMS}-\mathrm{FAB}^{+}\right) m / z: 268\left(\mathrm{MH}^{+}=28 \%\right), 219(20), 184$ (40), 154 (100), 136 (70). Elemental analysis (WAS): Calcd for $\mathrm{C}_{12} \mathrm{H}_{13} \mathrm{NO}_{2} \mathrm{~S}_{2}$ : C, 53.9; H, 4.9; N, 5.2. Found: C, 53.7; H, 4.8; N, 5.1\%.

## Experimental

### 4.0 General procedure for radical precursors 278a-I

## 4.1 $N$-BUTYLLITHIUM METHOD:

To a stirred solution of $N$-butyl-4-(substituted)-benzenesulfonamide 283 (1.0 eq.) in anhydrous tetrahydrofuran was added $n$-butyllithium ( 1.6 M in hexanes) (1.0 eq.) and 2-bromo-isobutyryl bromide 284 ( 1.0 eq.) at $-78^{\circ} \mathrm{C}$ (dry ice/acetone) overnight. The reaction was quenched with saturated ammonium chloride ( 10 mL ), and the product extracted with dichloromethane ( 200 mL ), followed by saturated sodium bicarbonate $(200 \mathrm{~mL})$. The aqueous phase was washed with dichloromethane $(2 \times 200 \mathrm{~mL})$ and the combined organic fractions were washed with saturated sodium chloride. The organic phase was dried with magnesium sulfate, and the solvent evaporated in-vacuo to yield a crude product. Purification of the crude product (petrol ether: ethyl acetate) furnished the radical precursor 278.

### 4.2 TRIETHYLAMINE METHOD

To a stirred solution of N -butyl-(substituted) benzenelsulfonamide $\mathbf{2 8 3}$ (1.0 eq.) in dry dichloromethane was added triethylamine (1.0 eq.) and 2-bromo-isobutyryl bromide 284 (1.0 eq.), under nitrogen at room temperature overnight. The reaction was quenched with distilled water ( 50 mL ), and the product extracted with diethyl ether ( $3 \times 50 \mathrm{~mL}$ ). The combined organic extracts were dried over magnesium sulfate and the solvent evaporated in vacuo to furnish the crude product. Purification with petrol ether: ethyl acetate, yield the radical precursor 278.

## Experimental

### 4.3 HÜNIG'S BASE METHOD

To a solution of $N$-butyl-(substituted)-benzenesulfonamide (1.0 eq.) 283 in dichloromethane, was added $N$-ethyldiisopropylamine (Hünig's base, 1.3 eq.) and 2-bromo-isobutyryl bromide (1.1 eq.) 284 at room temperature overnight. The reaction was quenched with distilled water ( 50 mL ), and the product was extracted with dichloromethane ( 3 x 50 mL ). The combined organic extracts were dried with magnesium sulfate and the solvent evaporated in-vacuo to yield the crude product. Purification with petrol ether: ethyl acetate furnished the radical precursor 278.

### 4.4 IMPROVED METHOD

When the radical precursor 283 ( 1.0 eq.), triethylamine ( 1.0 eq.) and the acid bromide 284 (3.0 eq.) are used, no eliminated product 286 is observed. Work up is same as for method 2.

## N - (2-Bromo-2-methyl-propionyl)- N -butyl-benzenesulfonamide 278a

Flash chromatography (petrol ether/ethyl acetate, 6:1) furnished N-(2-bromo-2-methyl-propionyl)-N-butyl-benzenesulfonamide 278a as a light yellow viscous solid $(13.17 \mathrm{~g}$, $31 \%$ ). IR (neat) $v_{\max }: 2955,1675,1346,1166,1069,723 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (400MHz/ $\mathrm{CDCl}_{3}, \delta$ ): 7.99-7.96 (app. d.t, $J=8.0$ and $2.0,2 \mathrm{H}, \mathrm{ArCH}$ ), 7.61-7.59 (m, 1 H , ArCH), 7.54-7.50 (m, 2H, ArCH) 4.19 (app. $\mathrm{t}, J=8.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $1.96-1.88(\mathrm{~m}, 8 \mathrm{H}$, $\mathrm{CH}_{2}$ and $\mathrm{C}\left(\mathbf{C H}_{3}\right)_{2}$ ) 1.46-1.37 (app. sxt., $\left.J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 0.99\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right)$. ${ }^{13} \mathrm{C}$ NMR (75.5MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 170.8$ ( $\mathbf{s}, \mathbf{C}=\mathrm{O}$ ), 139.7 ( $\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}-$ ), 133.9 (d, ArCH ),

## Experimental

## Experimental

### 5.0 General procedure for synthesis of radical procedures 369

$\mathrm{R}=$ alkyl

## 5.1 $N$-BUTYLLITHIUM METHOD:

To a stirred solution of $N$-alkyl-4-methylbenzenesulfonamide $\mathbf{3 7 4}$ (1.0 eq.) in anhydrous tetrahydrofuran was added $n$-butyllithium (1.6 M in hexanes) (1.0 eq.) and 2-bromoisobutyryl bromide 287 ( 1.0 eq.) at $-78^{\circ} \mathrm{C}$ (dry ice/acetone) overnight. The reaction was quenched with saturated ammonium chloride ( 10 mL ), and the product extracted with dichloromethane ( 200 mL ), followed by saturated sodium bicarbonate ( 200 mL ). The aqueous phase was washed with dichloromethane ( $2 \times 200 \mathrm{~mL}$ ) and the combined organic fractions were washed with saturated sodium chloride. The organic phase was dried with magnesium sulfate, and the solvent evaporated in-vacuo to yield a crude product. Purification of the crude product (petrol ether: ethyl acetate) furnished the radical precursor 369.

### 5.2 TRIETHYLAMINE METHOD

To a stirred solution of N -alky-4-methylbenzenesulfonamide 374 ( 1.0 eq.) in dry dichloromethane was added triethylamine (1 eq.) and 2-bromo-isobutyryl bromide 284 (1 eq.), under nitrogen at room temperature overnight. The reaction was quenched with distilled water ( 50 mL ), and the product extracted with diethyl ether ( $3 \times 50 \mathrm{~mL}$ ). The combined organic extracts were dried over magnesium sulfate and the solvent evaporated in vacuo to furnish the crude product. Purification with petrolether: ethyl acetate, yield the radical precursor 369 .

## Experimental

## $N$-(2-Bromo-2-methyl-propionyl)- $N$-ethyl-4-methyl-benzenesulfonamide 369a

Flash chromatography (petrol ether/ethyl acetate, 6:1) furnished N-(2-bromo-2-methyl-propionyl)-N-ethyl-4-methyl-benzenesulfonamide 369a as a light yellow crystallised solid (4.48g, $25 \%$ ). mp $98.5-98.6^{\circ} \mathrm{C}$. IR (neat) $v_{\text {max: }}$ : $2978,1709,1391,1163,811 \mathrm{~cm}^{-1}$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $7.86(\mathrm{~d}, J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 7.30(\mathrm{~d}, J=8.0,2 \mathrm{H}$, $\operatorname{ArCH}), 4.33\left(\mathrm{q}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.96\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.51(\mathrm{t}$, $\left.J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $171.5(\mathbf{s}, \mathbf{C}=\mathrm{O}), 144.5(\mathbf{s}, \mathbf{C}-\mathrm{Me})$, 136.5 (s, $\mathbf{C - S O} 2^{-}$), 129.3 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 128.6 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), $56.6\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 44.0$ $\left(\mathbf{t}, \mathbf{C H}_{2}\right), 31.8\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathbf{C H}_{3}\right)_{2}\right), 21.7\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 17.0\left(\mathbf{q}, \mathbf{C H}_{3}\right)$. LRMS (LSIMS-FAB $\left.{ }^{+}\right)$ $m / z: 350\left({ }^{81} \mathrm{Br}-\mathrm{MH}^{+}=12 \%\right), 348\left({ }^{79} \mathrm{Br}^{-\mathrm{MH}^{+}}=10\right), 154(100), 137$ (68). ## Experimental

## $N$-(2-Bromo-2-methyl-propionyl)- $N$-iso-butyl-4-methyl-benzenesulfonamide 369h

Previously synthesised by Fullaway. ${ }^{163}$ Flash Chromatography (6:1 petrol ether:ethyl acetate) furnished N -(2-bromo-2-methyl-propionyl)-N-iso-butyl-4-methyl-benzenesulfonamide $\mathbf{3 6 9 h}$ as pale yellow crystallised solid (3.06g, $90 \%$ ) $\mathrm{mp} 91.3-91.5^{\circ} \mathrm{C}$. IR (neat) $v_{\max }: 2964,1813,1323,1159,1040$ and $812 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right)$ : $7.74(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 7.30(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 3.90(\mathrm{~d}, J=8.0,2 \mathrm{H} \mathrm{CH} 2)$, $2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.96\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right), 1.74-1.68(\mathrm{spt} ., J=7.0,1 \mathrm{H}, \mathrm{CH}), 1.07(\mathrm{~d}, J=$ 7.0, $\left.6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 176.00(\mathbf{s}, \mathbf{C}=\mathrm{O}), 165.76(\mathbf{s}, \mathbf{C}-\mathrm{Me})$, $143.32\left(\mathbf{s}, \mathbf{C}_{-} \mathrm{SO}_{2^{-}}\right), 129.70(2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}), 127.07(2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}), 55.01\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right)$, $50.55\left(\mathbf{t}, \mathbf{C H}_{2}\right), 30.01\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 19.88\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 28.44(\mathbf{d}, \mathbf{C H}) 20.25(\mathbf{q}$, $\left.\mathrm{ArCH}_{3}\right) . \operatorname{LRMS}(\mathrm{LSIMS}) m / z: 378\left({ }^{81} \mathrm{Br} \mathrm{M}^{+}=19 \%\right), 376\left({ }^{79} \mathrm{Br} \mathrm{M}^{+}=20 \%\right), 296$ (25), $228\left({ }^{79} \mathrm{Br} 100\right), 154$ (30), 137 (35).
$N$-(2-Bromo-2-methyl-propionyl)- $N$-sec-butyl-4-methyl-benzenesulfonamide 369i

Previously synthesised by Fullaway. ${ }^{163}$ Flash chromatography (6:1 petrol ether:ethyl acetate) furnished N -(2-bromo-2-methyl-propionyl)-N-sec-butyl-4-methyl-benzenesulfonamide $[\mathbf{3 6 9 i}]$ as a pale yellow crystallised solid $(2.88 \mathrm{~g}, 85 \%) \mathrm{mp} 105.4-105.5^{\circ} \mathrm{C}$.

## Experimental

IR (neat) $v_{\max }: 2971,1712,1297,1157,1090,663 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (400MHz, $\left.\mathrm{CDCl}_{3}, \delta\right)$ : 7.86 (d.t, $J=8.0$ and $2.0,2 \mathrm{H}, \mathrm{ArCH}), 7.29(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 4.61(\mathrm{app} . \mathrm{spt} . J=$ $7.0,1 \mathrm{H}, \mathrm{CH}), 2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.40-2.30(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}), 2.13-2.03(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}), 1.90$ $\left(\mathrm{s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right), 1.69\left(\mathrm{~d}, J=7.0, \mathbf{C H}_{3}\right), 1.03\left(\mathrm{t}, J=7.0 \mathrm{~Hz}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( 100 MHz , $\left.\mathrm{CDCl}_{3}, \delta\right): 176.6(\mathbf{s}, \mathbf{C}=\mathrm{O}), 143.2(\mathbf{s}, \mathbf{C}-\mathrm{Me}), 138.2\left(\mathbf{s}, \mathbf{C}-\mathrm{SO}_{2}-\right), 129.5(2 \mathrm{x} \mathrm{d}, \mathbf{C H}), 127.0$ $\left.(2 \times \mathrm{d}, \mathrm{CH}), 55.3\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 51.4(\mathbf{d}, \mathbf{C H}), 30.6\left(2 \times \mathrm{q}, \mathrm{CH}_{3}\right)_{2}\right), 30.2\left(\mathbf{t}, \mathrm{CH}_{2}\right) 21.6(2$ $\left.\mathrm{x} \mathbf{q}, \mathrm{CH}_{3}\right), 15.0\left(\mathbf{q}, \mathrm{CH}_{3}\right)$.

## 6.0 $\quad \mathrm{N}$-(Hetero)aryl-4-methylbenzene sulfonamides 381

### 6.1 TRIETHYLAMINE METHOD

To a stirred solution of $N$-(hetero)aryl-4-methylbenzenesulfonamide 380 ( 1.0 eq.) in dry dichloromethane was added triethylamine (1 eq.) and 2-bromo-isobutyryl bromide $\mathbf{2 8 4}$ (1 eq.), under nitrogen at room temperature overnight. The reaction was quenched with distilled water ( 50 mL ), and the product extracted with diethyl ether ( 3 x 50 mL ). The combined organic extracts were dried over magnesium sulfate and the solvent evaporated in vacuo to furnish the crude product. Purification with petrolether: ethyl acetate, yield the radical precursor 381.

## Experimental

## $N$-(2-Bromo-2-methyl-propionyl)-4-methyl- $N$-(4-methyl-benzyl)benzenesulfonamide 381a

$N$-(2-bromo-2-methyl-propionyl)-4-methyl-N-(4-methyl-benzyl)-benzenesulfonamide 381a obtained as a light brown crystallised solid (3.14g, 100\%). ## Experimental

### 7.0 Synthesis of cyclised and rearranged amides from radical precursors 278

### 7.1 General method for copper-mediated radical reactions

To a stirred solution of the radical precursor 278 (1.0 eq.) in dichloromethane (DCM) was added of tris-[(2-pyridyl)methyl]-amine (1.1 eq.) 279 and copper bromide ( 1.1 eq. ). The reaction was stirred under nitrogen at $37^{\circ} \mathrm{C}$, and monitored by TLC until the disappearance of starting material. Filtering the crude product through a silica plug with ethyl acetate quenched the reaction mixture. The solvent was evaporated in vacuo to yield an emerald green crude product. Purification by flash chromatography led to an isolation of both the cyclised and rearranged products. Reactions done in toluene were performed under inert atmosphere at reflux temperature unless otherwise stated.

## 2-(Phenyl)- $N$-butyl-isobutyramide 280a

Purification by column (petrol ether/ethyl acetate 8:1), furnished 2-(phenyl)-n-butylisobutyramide 280a as apple-white translucent spherical solid ( $0.13 \mathrm{~g}, 40 \%$ ). IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ $v_{\max }: 3359,2928,1643,1525,1365,1164,762 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (300MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 7.36$ (s, 4H, ArCH), 7.29-7.24 (m, 1H, ArCH), $5.18(\mathrm{~s}, 1 \mathrm{H}, \mathrm{NH}), 3.15\left(\mathrm{q}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right)$, 1.56 ( $\left.\mathrm{s}, 6 \mathrm{H}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.40-1.30$ (quin., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.26-1.14 (sxt., $J=7.0,2 \mathrm{H}$,

## Experimental

$\mathrm{CH}_{2}$ ), $0.84\left(\mathrm{t}, J=7.0 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{\mathbf{3}}\right) .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $177.4(\mathrm{~s}, \mathbf{C}=\mathrm{O})$, 145.3 (s, C-SO $2^{-}$), $128.6(\mathbf{d}, \mathrm{ArCH}), 127.0(2 \times \mathrm{d}, \mathrm{ArCH}), 126.4$ ( $2 \times \mathrm{d}$ d, ArCH ), $47.0(\mathrm{~s}$, $\left.\mathbf{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 39.4\left(\mathbf{t}, \mathrm{CH}_{2}\right), 31.5\left(\mathbf{t}, \mathrm{CH}_{2}\right), 29.7\left(2 \mathrm{x} \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.00\left(\mathbf{t}, \mathrm{CH}_{2}\right), 14.00(\mathbf{q}$, $\left.\mathrm{CH}_{3}\right)$. LRMS $\left(\mathrm{EI}^{+}\right) m / z: 220\left(100=\mathrm{M}^{+}\right), 120(100), 119(90), 105(95) . \mathrm{HRMS}\left(\mathrm{EI}^{+}\right)$ $m / z:\left(\mathrm{M}^{+}\right)$calcd for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{NO}, 219.1623$; found, 219.1624.
$N$-Butyl-3,3-dimethyl-1,3-dihydro-indol-2-one $290{ }^{190}$

Previously synthesised. Purification by flash chromatography furnished 1-butyl-3,3-dimethyl-1,3-dihydro-indol-2-one 290 as a transparent spherical film ( $0.14 \mathrm{~g}, 59 \%$ ). IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) v_{\text {max }}: 2962,2928,2868,1357,1133,749 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H} \operatorname{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right):$ 7.21 (app. q., $J=7.5,2 \mathrm{H}, \operatorname{ArCH}), 7.04(\mathrm{~m}, 1 \mathrm{H}, \operatorname{ArCH}), 6.87(\mathrm{~d}, J=7.0,1 \mathrm{H}, \mathrm{ArCH})$, $3.71\left(\mathrm{t}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right.$ ), 1.71-1.61 (app. quin., $\left.J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.44-1.31(\mathrm{~m}, 8 \mathrm{H}$, $\left.\mathrm{CH}_{\mathbf{2}}+\left(\mathrm{CH}_{3}\right)_{2}\right), 0.95\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR $\left(75.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 181.3(\mathbf{s}$, $\mathbf{C}=\mathrm{O}$ ), 142.1 (s, $\mathbf{C}-\mathrm{N}-$ ), 136.0 ( $\left.\mathbf{s}, \mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 127.6$ ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), 122.2 (d, ArCH ), 108.3 (d, ArCH$), 44.1\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 39.6\left(\mathbf{t}, \mathbf{C H}_{2}\right), 29.5\left(\mathbf{t}, \mathbf{C H}_{2}\right), 24.5\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathbf{C H}_{3}\right)_{2}\right)$, $20.1\left(\mathbf{t}, \mathrm{CH}_{2}\right)$, $14.1\left(\mathbf{q}, \mathrm{CH}_{3}\right)$. LRMS $\left(\mathrm{EI}^{+}\right) m / z: 218\left(\mathrm{M}-\mathrm{SO}_{2}=13 \%\right) 217\left(\mathrm{M}-\mathrm{SO}_{2}=\right.$ 82\%), 174 (82), 146 (100), 130 (23). HRMS (LSIMS-FAB ${ }^{+}$) $m / z:\left(\mathrm{M}^{+}\right)$calcd for $\mathrm{C}_{14} \mathrm{H}_{19} \mathrm{NO}, 217.1467$; found, 217.1459.

## Experimental

## Authentic synthesis of the rearranged amide

## 2-Methyl-2-p-tolyl-propionic acid ethyl ester $348{ }^{219}$

Synthesised according to Küntzel et al. procedure. To a solution of anhydrous dimethylformamide (DMF) ( 25 mL ), was added ethyl-p-tolylacetate ( $10 \mathrm{~g}, 9.9 \mathrm{~mL}, 56$ mmol) (Flask A). In a separate flask (B) was added sodium hydride in mineral oil (60\%) ( $7.85 \mathrm{~g}, 196 \mathrm{mmol}$ ) which was thrice washed in pentane under a nitrogen atmosphere and the mineral oil decanted. To flask B between $5-10{ }^{\circ} \mathrm{C}$ was added anhydrous dimethylformamide (DMF) (300 mL), and methyl iodide (CAUTION: Carcinogenic) $(12.16 \mathrm{~g}, 196 \mathrm{mmol})$ to give a dark grey turbid solution. Ethyl-p-tolylacetate (Flask A) was added dropwise over one hour. The mixture was stirred under nitrogen at room temperature for 46 hours. The mixture was quenched with ethanol $(100 \mathrm{~mL})$ and saturated ammonium chloride ( 100 mL ). Extraction with ether ( 5 x 100mL) and washing the organic layer with water ( $5 \times 100 \mathrm{~mL}$ ), to neutrality, and drying over anhydrous magnesium sulfate. The solvent was removed in-vacuo to an light reddish-orange mobile oil ( 6.78 g ). The desired product 2-methyl-2-p-tolyl-propionic acid ethyl ester 348 was furnished as a light greenish-yellow oil $(2.36,20 \%)$ following flash chromatography (petrol ether:diethyl ether 20:1).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 7.24-7.15 (app. d.t. $J=8.0$ and $2.0,2 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 7.09 (app. d, $J=8.0,2 \mathrm{H}, \mathrm{ArCH}_{2}$ ), 4.14-4.05 (app. q, $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 2.15 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}$ ), $1.54\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.21-1.12\left(\mathrm{t} J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}\right.$ NMR (100MHz, $\left.\mathrm{CDCl}_{3}, \delta\right)$ : 176.9 (s, $\mathbf{C}=\mathrm{O}$ ), $141.2(\mathbf{s}, \mathbf{C}-\mathrm{Me}), 136.2\left(\mathbf{s}, \mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 129.0(2 \times \mathrm{d}, \mathrm{ArCH}), 125.5(2 \mathrm{x}$ d, ArCH$), 60.7\left(\mathbf{t}, \mathrm{CH}_{2}\right), 29.7\left(2 \mathrm{x} \mathbf{q}, \mathrm{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 20.9\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 15.0\left(\mathbf{q}, \mathbf{C H}_{3}\right)$.

## Experimental

## $\boldsymbol{\alpha}, \boldsymbol{\alpha}, 4$-Trimethylbenzeneacetic acid $350{ }^{222}$

Commercially available from Interchim [20430-18-6]. Previously synthesised by Smith III et. al. ${ }^{220}$ To a flask containing the gem ester ( 1.5 g ) with potassium hydroxide pellets ( 0.61 g ) was added absolute ethanol ( 50 mL ), and the solution was stirred at reflux for six days. The solvent was removed in-vacuo to yield an orange-yellow solid $(2.30 \mathrm{~g})$. The crude solid was treated with diethyl ether ( $2 \times 125 \mathrm{~mL}$ ) and then acidified down to pH 2 with hydrochloric acid $(2 \mathrm{M} \mathrm{HCl})$. The organic phase was dried over anhydrous magnesium sulfate. The solvent was removed in-vacuo to furnish a yellow solid (1.20g) as $\alpha, \alpha$, 4-trimethylbenzeneacetic acid 350. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 9.4 (bs, 1 H , COOH), 7.10 (d.t, $J=8.0$ and 2.0, $2 \mathrm{H}, \operatorname{ArCH}$ ), $6.99(\mathrm{t}, J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 2.19(\mathrm{~s}, 3 \mathrm{H}$, $\left.\operatorname{ArCH}_{3}\right), 1.44\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right) .{ }^{13} \mathrm{C}$ NMR (100MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 177.0(\mathrm{~s}, \mathbf{C}=\mathrm{O}), 141.9(\mathrm{~s}$, C-Me), 137.0 (s, $\left.\mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$, 129.2 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 125.7 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 46.2 ( $\mathbf{s}, \mathbf{C}-$ $\left.\left(\mathrm{CH}_{3}\right)_{2}\right), 26.6\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 21.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right)$.

## 2-Methyl-2-p-tolyl-propionyl chloride $351{ }^{222}$

Previously synthesised by Buckle et. al. ${ }^{247}$ To a flask containing the gem acid $(0.40 \mathrm{~g})$ was added oxalyl chloride $(0.88 \mathrm{~g}, 0.60 \mathrm{~mL})$ and the mixture refluxed vigourously for 24h. The excess oxalyl chloride was removed in-vacuo to furnish 2-methyl-2-p-tolylpropionyl chloride $\mathbf{3 5 1}$ as a yellow oil $(0.14 \mathrm{~g}){ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right)$ : 7.16-7.08 $(\mathrm{m}, 4 \mathrm{H}, \mathrm{ArCH}), 2.32\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.58\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)\right.$.

## Experimental

Authentic Synthesis $\boldsymbol{N}$-Butyl-2-p-tolyl-isobutyramide 280e ${ }^{222}$

To a stirred solution of 2-methyl-2-phenyl-propionyl chloride $351(0.02 \mathrm{~g}, 0.1 \mathrm{mmol})$ in diethyl ether ( 2 mL ), was added $n$-butylamine $(0.01 \mathrm{~mL}, 0.3 \mathrm{mmol})$ at room temperature for 2 days. The reaction was quenched with water $(5 \mathrm{~mL})$ and the organic phase extracted with diethyl ether ( $5 \times 5 \mathrm{~mL}$ ), and dried with anhydrous magnesium sulfate. The solvent was removed in-vacuo to furnish $N$-butyl-2-p-tosyl-isobutyramide $\mathbf{2 8 0} \mathbf{e}$ a yellow viscous solid $(0.012 \mathrm{~g}, 26 \%) .{ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.18$ (d.t, $J=8.0$ and $2.0,2 \mathrm{H}, \operatorname{ArCH}), 7.08(\mathrm{~d}, J=8.0,2 \mathrm{H}, \operatorname{ArCH}), 5.05(\mathrm{bs}, 1 \mathrm{H}, \mathrm{NH}), 3.07(\mathrm{q}, J=7.0$, $\left.2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.27\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.47\left(\mathrm{~s}, 6 \mathrm{H}, 2 \times \mathrm{CH}_{3}\right), 1.31-1.24$ (quin. $J=7.0,2 \mathrm{H}$, $\mathrm{CH}_{2}$ ), 1.19-1.09 (app. sxt., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.78\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C} \mathrm{NMR}$ (100MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 177.6(\mathbf{s}, \mathbf{C}=\mathrm{O}), 142.3(\mathbf{s}, \mathbf{C}-\mathrm{Me}), 136.6\left(\mathbf{s}, \mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 129.3(2 \mathrm{x}$ d, $\mathrm{Ar} \mathbf{C H}), 126.4(2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}), 46.7\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 39.4\left(\mathbf{t}, \mathrm{CH}_{2}\right), 31.6\left(\mathbf{t}, \mathrm{CH}_{2}\right), 27.2(2$ x $\left.\mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.9\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 20.0\left(\mathbf{t}, \mathbf{C H}_{2}\right), 14.8\left(\mathbf{q}, \mathbf{C H}_{3}\right)$. LRMS (LSIMS-FAB $\left.{ }^{+}\right)$ $m / z: 234\left(\mathrm{MH}^{+}=100 \%\right), 154(100), 137(66), 133(22), 120(12)$. HRMS (LSIMS-FAB) $m / z:\left(\mathrm{MH}^{+}\right)$calcd for $\mathrm{C}_{15} \mathrm{H}_{24} \mathrm{NO}, 234.1858$; found, 234.1868 .

## Authentic Synthesis of 1-butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one

$\boldsymbol{N}$ - $\boldsymbol{n}$-Butyl- $\boldsymbol{p}$-toluidine $340{ }^{209}$

Commercially available from Wako Pure Chemicals [10387-24-3]. A flask (A) containing sodium hydride in $60 \%$ mineral oil was thrice washed with pentane, and the

## Experimental

oil decanted. In a separate flask (B) was added p-toluidine 339 ( 10 g ) in dimethylformamide (DMF) ( 50 mL ) which was transferred via syringe to flask (A) which formed a light grey turbid solution. The solution turned dark brown over one hour. Addition of $n$-butyl iodide (CAUTION: CARCINOGENIC), to flask (A) gave a brownish-yellow solution. The solution was stirred overnight at room temperature where upon the solution had become olive green. The reaction mixture was quenched with 95\% ethanol and strong effervensing was observed. The solution had changed to dark brown. With addition of saturated ammonium chloride a bright orange solution was obtained. Work up consisted of ether ( $5 \times 50 \mathrm{~mL}$ ) followed by water ( 10 x 50 mL ), drying the organic phase over anhydrous magnesium sulfate and removal of the solvent in-vacuo to give an orange oil. Purification via distillation (bp $143{ }^{\circ} \mathrm{C} / 10 \mathrm{Torr}$ ) gave dark brown oil identified as $N$-n-butyl-p-toluidine 340. ${ }^{1} \mathrm{H}$ NMR (400MHz, $\mathrm{CDCl}_{3}, \delta$ ): 6.90 (d, $J=8.0$, $2 \mathrm{H}, \mathrm{ArCH}), 6.45$ (d.t, $J=8.0$ and $2.5,2 \mathrm{H}, \mathrm{ArCH}), 3.01\left(\mathrm{t}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.16(\mathrm{~s}$, $3 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 1.55-1.48 (q, $\left.J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.40-1.30\left(\mathrm{sxt} . J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 0.88(\mathrm{t}, J$ $\left.=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 146.3 ( $\mathbf{s}, \mathbf{C}-\mathrm{N}-$ ), 129.7 ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), 126.3 (s, C-Me), 122.9 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), $44.1\left(\mathbf{t}, \mathbf{C H}_{2}\right), 31.8\left(\mathbf{t}, \mathbf{C H}_{2}\right), 20.4\left(\mathbf{t}, \mathbf{C H}_{2}\right), 20.4$ $\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 15.0\left(\mathbf{q}, \mathrm{CH}_{3}\right)$.

## 2-Bromo- N -butyl-2-methyl- N -p-tolyl-propionamide $341^{210}$

To a flask containing $N$-butyl- $p$-toluidine $\mathbf{3 4 0}$ in diethyl ether ( 50 mL ) was added triethylamine ( 1.41 g ) and 2-bromo-2-isobutyryl bromide ( 5.5 mL ). The reaction mixture

## Experimental

was stirred for 3 hours. The reaction mixture was quenched with ether ( $2 \times 100 \mathrm{~mL}$ ) followed by water ( 100 mL ) and dilute hydrochloric acid ( $1 \mathrm{M}, 100 \mathrm{~mL}$ ). The organic phase was washed with sodium bicarbonate and the organic phase dried over anhydrous magnesium sulfate. The solvent was removed in-vacuo to give brown viscous oil $(1.65 \mathrm{~g})$. Flash chromatography (petrol ether:ethyl acetate 6:1) furnished 2-bromo-N-butyl-2-methyl-N-p-tolyl-propionamide 341 as a yellow oil $(0.39 \mathrm{~g}, 31 \%) .{ }^{1} \mathrm{H}$ NMR ( 300 MHz , $\left.\mathrm{CDCl}_{3}, \delta\right): 7.29-7.12(\mathrm{~m}, 4 \mathrm{H}, \mathrm{ArCH}), 3.65\left(\mathrm{t}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.39(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH})$, $1.70\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathbf{C H}_{3}\right)_{2}\right), 1.57-1.51$ (app. quin., $J=7.0,2 \mathrm{H}, \mathbf{C H}_{2}$ ), 1.37-1.25 (app. sxt., $J=$ $7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.89\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 169.5$ (s, $\mathbf{C = O}$ ), 139.9 ( $\mathbf{s}, \mathbf{C}-\mathrm{N}-$ ), 137.5 (s, $\mathbf{C - M e}$ ), 129.4 (4 x d, ArCH ), 59.0 ( $\left.\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 53.2$ $\left(\mathbf{t}, \mathrm{CH}_{2}\right), 29.8\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 28.9\left(\mathbf{t}, \mathrm{CH}_{2}\right), 20.9\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 19.8\left(\mathbf{t}, \mathbf{C H}_{2}\right), 13.7(\mathbf{q}$, $\mathrm{CH}_{3}$ ). LRMS (LSIMS-FAB ${ }^{+}$) $m / z: 314\left({ }^{81} \mathrm{Br} \mathrm{MH}^{+}=98 \%\right)$, $313\left({ }^{81} \mathrm{Br} \mathrm{M}^{+}=60\right), 312$ $\left({ }^{79} \mathrm{Br} \mathrm{MH}^{+}=100\right), 311\left({ }^{79} \mathrm{Br} \mathrm{M}^{+}=40\right), 232$ (43), 154 (70), 138 (30), 136 (50). HRMS (LSIMS-FAB ${ }^{+}$) $m / z$ : calcd for $\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{BrNO}, 311.0885$; found, 311.0882.

## 1-Butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one $333{ }^{210}$

Anhydrous aluminium chloride was kept under a stream of nitrogen and to a single necked flask was added $(0.54 \mathrm{~g})$ and the precursor $341(0.50 \mathrm{~g})$. An air condenser was attached and the mixture was heated to $50^{\circ} \mathrm{C}$ for 10 min , then maintained at $160^{\circ} \mathrm{C}$ for 1h. A black viscous solid was obtained upon cooling. The reaction mixture was washed with water ( $5 \times 50 \mathrm{~mL}$ ) furnished a yellow solution, and the organic phase extracted with

## Experimental

diethyl ether. The ethereal phase was dried with anhydrous magnesium sulfate, and the solvent removed in-vacuo to furnish a yellow oil $(0.41 \mathrm{~g})$. Purification from flash chromatography (petrol ether:ethyl acetate 9:1) furnished 1-butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one 333 as a light yellow oil ( $0.17 \mathrm{~g}, 46 \%$ ). IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) v_{\text {max }}$ : 2927, 1641, 1510,1108 and $822 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\left.400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 6.94(\mathrm{~d}, J=7.0,2 \mathrm{H}, \mathrm{ArCH})$, 6.64 (app. d, $J=7.0,1 \mathrm{H}, \mathrm{ArCH}), 3.60\left(\mathrm{t}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.24\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.59-$ 1.52 (quin., $\left.J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.32-1.22\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{CH}_{2}+\left(\mathrm{CH}_{3}\right)_{2}\right), 0.85(\mathrm{t}, J=7.0,3 \mathrm{H}$, $\mathrm{CH}_{3}$ ). ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ) 180.1 ( $\mathbf{s}, \mathbf{C}=\mathrm{O}$ ), 138.6 ( $\mathbf{s}, \mathbf{C}-\mathrm{N}-$ ), 135.0 ( $\mathbf{s}, \mathbf{C}-\mathrm{Me}$ ), 130.6 (s, $\left.\mathbf{C - C}\left(\mathrm{CH}_{3}\right)_{2}\right) 126.7$ (d, ArCH$), 122.2$ (d, ArCH$), 107.0$ (d, ArCH), 43.0 (s, C$\left.\left(\mathrm{CH}_{3}\right)_{2}\right)$, $38.5\left(\mathbf{t}, \mathrm{CH}_{2}\right)$, $28.5\left(\mathbf{t}, \mathrm{CH}_{2}\right), 23.4\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 19.7(\mathbf{t}$, $\left.\mathbf{C H}_{2}\right), 13.5\left(\mathbf{q}, \mathbf{C H}_{3}\right) ; m / z($ LSIMS $) 232\left(\mathrm{MH}^{+}=32 \%\right), 207(27), 165(11), 154$ (100), 136 (80), 120 (27).

1-Butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one 333
Copper-mediated radical reaction

To a three necked RB flask was added 341 ( $0.58 \mathrm{~g}, 1.0$ eq.), tris-(2-pyridylmethyl)-amine $279(0.67 \mathrm{~g}, 1.1 \mathrm{eq})$ and copper bromide $(0.39 \mathrm{~g}, 1.1 \mathrm{eq}$.$) in toluene (16 \mathrm{~mL})$ and the reaction mixture stirred under nitrogen at $120{ }^{\circ} \mathrm{C}$ for 24 h . The crude product was filtered through a silica plug with ethyl acetate to yield a pale yellow oil $(0.42 \mathrm{~g}, 98 \%)$ as 1-butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one 333. IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) v_{\max }$ 2927, 1706, 1494, $1192,803 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR (400MHz, $\left.\mathrm{CDCl}_{3}\right) 6.93(\mathrm{~d}, J=7.0,2 \mathrm{H}, \operatorname{ArCH}), 6.65(\mathrm{~d}, J=$

Discernible data for butyl-3,3,6-trimethyl-1,3-dihydroindol-2-one 336

## Butyl-m-tolylamine $\mathbf{3 4 3}{ }^{212}$

Procedure same as above for $\mathbf{3 4 0}$. Distilled at $114^{\circ} \mathrm{C} / 10$ Torr to furnish green mobile oil (3.0g, 20\%). ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 7.14-7.06 (m, 1H, $\operatorname{ArCH}$ ), 6.55 (app. d. $J=$ $7.0,1 \mathrm{H}, \mathrm{ArCH}), 6.46$ (app. d. $J=7.0,2 \mathrm{H}, \mathrm{ArCH}), 3.56(\mathrm{bs}, 1 \mathrm{H}, \mathrm{NH}), 3.14(\mathrm{t}, J=7.0$, $\left.2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.68-1.59\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{3}\right), 1.50-1.40\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.00$ (app. t, $J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}$ ).

## 2-Bromo-N-butyl-2-methyl- $\boldsymbol{N}$-m-tolyl-propionamide $345{ }^{210}$

Same procedure as for 341. Flash chromatography (petrol ether: ethyl acetate 6:1) furnished 2-bromo-N-butyl-2-methyl-N-m-tolyl-propionamide $\mathbf{3 4 5}$ as yellow oil (1.65g). ${ }^{1} \mathrm{H} \operatorname{NMR}\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 7.35-7.13(\mathrm{~m}, 4 \mathrm{H}, \mathrm{ArCH}), 3.67\left(\mathrm{t}, J=7.5,2 \mathrm{H}, \mathrm{CH}_{3}\right)$,

## Experimental

$2.35\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.00\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.61-1.50\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.38-1.32(\mathrm{~m}, 2 \mathrm{H}$, $\mathbf{C H}_{2}$ ), $0.90\left(\mathrm{t}, J=7.5,3 \mathrm{H}, \mathrm{CH}_{3}\right)$.

## Butyl-3,3,6-trimethyl-1,3-dihydroindol-2-one 336 ${ }^{210}$

## $\mathrm{AlCl}_{3}$ anhydrous reaction

Same procedure as used for 333. Flash chromatography (petrol ether:ethyl acetate 9:1) furnished butyl-3,3,5-trimethyl-1,3-dihydroindol-2-one $\mathbf{3 3 6}$ inseparable mixture as colourless oil $(0.02 \mathrm{~g}) .{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 7.08(\mathrm{~d}, J=7.5,1 \mathrm{H}, \mathrm{ArCH}), 6.85$ $(\mathrm{d}, J=7.5,1 \mathrm{H}, \operatorname{ArCH}), 6.68(\mathrm{~s}, 1 \mathrm{H}, \operatorname{ArCH}), 3.69\left(\mathrm{t}, J=7.5,2 \mathrm{H}, \mathrm{CH}_{3}\right), 2.38(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{ArCH}_{3}\right), 1.69-1.60\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.40-1.30\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{CH}_{\mathbf{2}}+\left(\mathrm{CH}_{3}\right)_{2}\right), 0.94(\mathrm{t}, J=7.5,3 \mathrm{H}$, $\mathrm{CH}_{3}$ ).

## Butyl-3,3,6-trimethyl-1,3-dihydroindol-2-one 336

## Copper (I) bromide/TPA reaction

Same procedure as used for 333. Purification from flash chromatography (petrol ether: ethyl acetate 1:6) furnished $\mathbf{3 3 6}$ as a clear liq ( $0.04 \mathrm{~g}, 10 \%$ ); $\mathbb{R}$ (neat) $v_{\max } 2963,1713$, 1609, 1384, 1117 and $810 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (300MHz, $\left.\mathrm{CDCl}_{3}, \delta\right) 7.08(\mathrm{~d}, J=7.5,1 \mathrm{H}$, $\operatorname{ArCH}), 6.85(\mathrm{~d}, J=7.5,1 \mathrm{H}, \operatorname{ArCH}), 6.68(\mathrm{~s}, 1 \mathrm{H}, \operatorname{ArCH}), 3.69\left(\mathrm{t}, J=7.5,2 \mathrm{H}, \mathrm{CH}_{2}\right)$, $2.38\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.69-1.61\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 1.42-1.31\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{CH}_{2}+\left(\mathrm{CH}_{3}\right)_{2}\right), 0.95(\mathrm{t}$, $\left.J=7.5,3 \mathrm{H}, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 182.5(\mathbf{s}, \mathbf{C}=\mathrm{O}), 142.1(\mathrm{~s}, \mathbf{C}-\mathrm{N}-)$,

## Experimental

137.6 (s, C-Me), 133.2 (s, $\left.\mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$, 122.7 (d, ArCH ), 122.1 (d, ArCH ), 109.3 (d, $\mathrm{ArCH}), 43.9\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 39.5\left(\mathbf{t}, \mathbf{C H}_{2}\right), 31.8\left(\mathbf{t}, \mathbf{C H}_{2}\right), 29.6\left(\mathbf{t}, \mathbf{C H}_{2}\right), 21.8(2 \mathrm{x} \mathbf{q}$, $\left.\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 14.9\left(\mathbf{q}, \mathrm{CH}_{3}\right)$.
$N$-Butyl-2,4,6-trimethyl-phenyl-isobutryramide $280 f$

Purification by column chromatography (petrol ether: ethyl acetate 6:1) furnish $N$-butyl-2,4,6-trimethyl-phenyl-isobutryramide 280f and trace of $N$-butyl-2,4,6-trimethylbenzenesulphonamide $278 f(1.0: 0.1)$ as a colourless oil $(0.05 \mathrm{~g}, 10 \%)$. IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) v_{\text {max }}$ : $3316,2958,1736,1521,1161,850 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (400MHz; $\left.\mathrm{CDCl}_{3}, \delta\right) 6.80(\mathrm{~s}, 2 \mathrm{H}$, ArCH), 5.28 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{NH}$ ), 3.18 ( $\mathrm{q}, J=7.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2}$ ), 2.35 ( $\left.\mathrm{s}, 6 \mathrm{H}, 2 \times \mathrm{ArCH}_{3}\right), 2.23$ (s, 3H, $\mathrm{ArCH}_{3}$ ), $1.62\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right), 1.46-1.37$ (quin., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.30-1.21 (sxt, $\left.J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 0.88\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 180.3(\mathbf{s}$, $\mathbf{C}=\mathbf{O}$ ), 138.2 (s, $\left.\mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 137.8$ ( $2 \mathrm{x} \mathrm{s}, \mathbf{C}-\mathrm{Me}$ ), 135.8 (s, $\mathbf{C}-\mathrm{Me}$ ), 131.9 (d, ArCH ), 131.9 (d, ArCH), $49.7\left(\mathbf{s}, \mathbf{C}-\left(\mathrm{CH}_{3}\right)_{2}\right), 39.8\left(\mathbf{t}, \mathbf{C H}_{2}\right), 31.4\left(\mathbf{t}, \mathbf{C H}_{2}\right), 30.9\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 28.7$ $\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 23.4\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.3\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 20.0\left(\mathbf{t}, \mathrm{CH}_{2}\right), 14.7\left(\mathbf{q}, \mathbf{C H}_{3}\right)$. ### 8.0 Synthesis of cyclised and rearranged amides from radical precursors 369

370

371

372

### 8.1 General method for copper-mediated radical reactions

To a stirred solution of the radical precursor 369 (1.0 eq.) in dichloromethane (DCM) was added of tris-[(2-pyridyl)methyl]-amine (1.1 eq.) 279 and copper bromide ( 1.1 eq. ). The reaction was stirred under nitrogen at $37^{\circ} \mathrm{C}$, and monitored by TLC until the disappearance of starting material. Filtering the crude product through a silica plug with ethyl acetate quenched the reaction mixture. The solvent was evaporated in vacuo to yield an emerald green crude product. Purification by flash chromatography led to an isolation of both the cyclised and rearranged products. Reactions done in toluene were performed under inert atmosphere at reflux temperature unless otherwise stated.

## Experimental

## Authentic synthesis of $\boldsymbol{N}$-ethyl-2-tolyl-isobutyramide 370a ${ }^{222}$

General method: To a single-necked RB flask was added the gem-acid chloride $\mathbf{3 5 1}$ ( 0.02 g ) in diethyl ether ( 2 mL ). Ethylamine 373a ( $0.01 \mathrm{~g}, 3.0$ eq.) was added dropwise, and a turbid solution was observed. The reaction mixture was stirred for 48h. The reaction was quenched with water ( $3 \times 5 \mathrm{~mL}$ ) followed by diethyl ether ( $5 \times 5 \mathrm{~mL}$ ). The organic layer was dried over anhydrous magnesium sulfate, and the solvent removed invacuo to furnish a yellow viscous solid ( 0.012 g ) as N -ethyl-2-p-tolyl-isobutyramide 370a. IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) v_{\text {max }}: 3370,2971,1706,1513,1130,820 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (400MHz, $\left.\mathrm{CDCl}_{3}, \delta\right): 7.24(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 7.16(\mathrm{~d}, J=8.0,2 \mathrm{H}, \mathrm{ArCH}), 5.14(\mathrm{bs}, 1 \mathrm{H}, \mathrm{NH})$, 3.20 (quin., $J=7.0,2 \mathrm{H}, \mathrm{CH}$ ), $2.34\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.54\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right), 1.02(\mathrm{t}, J=7.0$, $\left.3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 177.6(\mathbf{s}, \mathbf{C}=\mathrm{O}), 142.3(\mathbf{s}, \mathbf{C}-\mathrm{Me}), 136.6(\mathbf{s}, \mathbf{C}-$ $\left.\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$, 129.4 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 126.4 ( $\left.2 \times \mathrm{d}, \mathrm{ArCH}\right), 46.6\left(\mathbf{s}, \mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 34.6$ (t, $\left.\mathbf{C H}_{2}\right), 27.2\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 21.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 13.0\left(\mathbf{q}, \mathrm{CH}_{3}\right)$. LRMS (LSIMS-FAB $\left.{ }^{+}\right)$ $m / z: 206\left(\mathrm{M}^{+}=57 \%\right), 204(100), 154$ (87), 136 (62), 124 (10). ## Experimental

## Authentic synthesis of $N$-isobutyl-2-p-tolyl-isobutyramide ${ }^{222} \mathbf{3 7 0 g}$

General method: To a single-necked RB flask was added the acid chloride $351(0.02 \mathrm{~g})$ in diethyl ether ( 2 mL ). Iso-butylamine $\mathbf{3 7 4 g}$ ( $0.01 \mathrm{~g}, 3.0 \mathrm{eq}$,) was added dropwise, and a turbid solution was observed. The reaction mixture was stirred for 48 h . The reaction was quenched with water ( $3 \times 5 \mathrm{~mL}$ ) followed by diethyl ether ( $5 \times 5 \mathrm{~mL}$ ). The organic layer was dried over anhydrous magnesium sulfate, and the solvent removed in-vacuo to furnish a yellow viscous solid ( 0.016 g ) as $N$-isobutyl-2-p-tolyl-isobutyramide $\mathbf{3 7 0 g} .{ }^{1} \mathrm{H}$ NMR (400MHz, $\left.\mathrm{CDCl}_{3}, \delta\right) 7.19$ (d.t, $J=8.0$ and 3.0, 2H, $\operatorname{ArCH}$ ), 7.09 (d, $J=8.0,2 \mathrm{H}$, $\operatorname{ArCH}), 5.10(\mathrm{bs}, 1 \mathrm{H}, \mathrm{NH}), 2.90\left(\mathrm{t}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.27\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.61-1.52$ (spt., $J=7.0,1 \mathrm{H}, \mathrm{CH}), 1.48\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right), 0.70\left(\mathrm{~d}, J=7.0,6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right) ;{ }^{13} \mathrm{C}$ NMR (100MHz, $\left.\mathrm{CDCl}_{3}, \delta\right) 177.9$ (s, C=O), 142.5 ( $\left.\mathbf{s}, \mathbf{C}-\mathrm{Me}\right), 136.9\left(\mathbf{s}, \mathbf{C}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 129.9$ (2 x d, $\operatorname{ArCH}$ ), 126.7 ( $2 \times \mathrm{x}$ d, ArCH ), "not observed" $\left(\mathbf{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$, $\left.47.2(\mathbf{t}, \mathbf{C H})_{2}\right), 28.7(\mathbf{s}, \mathbf{C H})$, $27.4\left(2 \times \mathbf{q}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 20.2\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 19.5\left(2 \times \mathbf{q}, \mathrm{CH}_{3}\right):$ LRMS $\left(\mathrm{LSIMS}-\mathrm{FAB}^{+}\right) \mathrm{m} / \mathrm{z}$ $233\left(\mathrm{M}^{+}=100 \%\right), 154$ (100), 137 (74), 120 (12); HRMS (LSIMS-FAB $\left.{ }^{+}\right)$Calc for $234.1858\left(\mathrm{MH}^{+}\right)$calc for $\mathrm{C}_{15} \mathrm{H}_{23} \mathrm{NO}$ Found 234.1858.
9.0 Synthesis of radical precursors 396, 407, 408, 406 and 413

## 9.1 $N$-butyllithium method:

To a stirred solution of $N$-alkyl-4-methylbenzenesulfonamide 284e (1.0 eq.) in dry dichloromethane was added n-butyllithium (1.1M) (1.0 eq.) and acid halide (1.0 eq/) at $78{ }^{\circ} \mathrm{C}$ (dry ice/acetone) overnight. The reaction was quenched with saturated ammonium

## Experimental

chloride ( 10 mL ), and the product extracted with dichloromethane ( 200 mL ), followed by saturated sodium bicarbonate ( 200 mL ). The aqueous phase was washed with dichloromethane ( $2 \times 200 \mathrm{~mL}$ ) and the combined organic fractions were washed with saturated sodium chloride. The organic phase was dried with magnesium sulfate, and the solvent evaporated in-vacuo to yield a crude product. Purification of the crude product (petrol ether/ EtOAc) gave the radical precursor.

## $N$-Ethyl-4-methyl- $N$-trichloromethylbenzenesulfonamide 396

Flash chromatography (6:1 petrol ether/ethyl acetate) furnished N -ethyl-4-methyl- N trichloromethylbenzenesulfonamide $\mathbf{3 9 6}$ as a white crystallised solid ( $2.5 \mathrm{~g}, 84 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 7.91$ (d.t, $J=8.0$ and $\left.2.0,2 \mathrm{H}, \operatorname{ArCH}\right), 7.33(\mathrm{~d}, J=8.0$, $2 \mathrm{H}, \mathrm{ArCH}), 4.33\left(\mathrm{q}, J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.45\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 1.55\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right)$. ${ }^{13} \mathrm{C}^{\mathrm{NMR}}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 158.8$ (s, $\mathbf{C}=\mathrm{O}$ ), 145.6 ( $\mathbf{s}, \mathbf{C}-\mathrm{Me}$ ), 134.9 (s, $\mathbf{C}-\mathrm{SO}_{2}$ ), 129.5 ( $2 \times \mathrm{d}$ d, ArCH ), 129.1 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 92.5 ( $\mathbf{s}, \mathbf{C C l}_{3}$ ) $44.8\left(\mathbf{t}, \mathbf{C H}_{2}\right)$, 21.7 (q, $\left.\mathrm{ArCH}_{3}\right), 15.5\left(\mathbf{q}, \mathbf{C H}_{3}\right) ;$ LRMS (LSIMS-FAB $\left.{ }^{+}\right) \mathrm{m} / \mathrm{z} 343\left(\mathrm{M}^{+}=10 \%\right)$, 155 (100), 137 (72), 136 (66), 120 (13). HRMS (LSIMS-FAB ${ }^{+}$) $m / z:\left(\mathrm{M}^{+}\right)$calcd for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{Cl}_{3} \mathrm{NO}_{3} \mathrm{~S}$; 343.9681, found 343.9671 .

## Experimental

## $N$-Butyl-2,2,2-trichloro- $N$-tolyl-acetamide 407

## Discernible data:

Flash chromatography (6:1 petrol ether/ethyl acetate) furnished N -butyl-2,2,2-trichloro-$N$-tolyl-acetamide 407 as a dark yellow oil (1.56g, $82 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ) 7.12 (s, 4H, $\operatorname{ArCH}$ ), 3.67 (bs, $2 \mathrm{H}, \mathrm{CH}_{2}$ ), 2.31 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 1.57-1.46 (quin. $J=7.0$, 2H, CH2 $)$, 1.31-1.17 (sxt, $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.83\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right.$ ). C-N-), 133.9 (s, C-Me), 129.7 ( $2 \times \mathrm{x}$ d, ArCH ), 120.3 ( 2 x d, ArCH ), 67.0 (d, CH), 21.0 (q, $\operatorname{ArCH})$. LRMS $\left(\mathrm{EI}^{+}\right) m / z: 217\left(\mathrm{M}^{+}=70\right), 202(12), 146$ (15), 134 (100), 106 (78).

### 5.10 General reactions

## $N$-Butyl- $N$-(2-methylacryloyl)-benzenesulfonamide 286a

To a stirred solution of $N$-butyl benzenesulfonamide 283a ( $0.21 \mathrm{~g}, 0.97 \mathrm{mmol}$ ) in anhydrous dichloromethane (DCM) ( 10 mL ) was added via syringe methacryloyl chloride $2850.09 \mathrm{~mL}, 0.94 \mathrm{mmol})$ followed by triethylamine (TEA) ( $0.13 \mathrm{~mL}, 0.94 \%$ ). The solution became turbid and was stirred at room temperature under nitrogen for 3 h . The crude mixture was quenched with water ( 50 mL ) followed by extraction of the product with diethyl ether ( $3 \times 50 \mathrm{~mL}$ ). The organic layer was dried over anhydrous magnesium sulfate and the solvent removed in-vacuo, to furnish a yelow oil. Purification via flash chromatography (petrol ether:ethyl acetate 6:1) furnished $N$-butyl- $N$-(2-methylacryloyl)-benzenesulfonamide 286a as a colourless oil (0.08g, 79\%). IR (neat) $v_{\max } 2959,1686,1353,1168,1026$ and $686 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR (300MHz, $\mathrm{CDCl}_{3}$, ס) $7.89(\mathrm{~d}, J=7.0,2 \mathrm{H}, \operatorname{ArCH}), 7.61($ app. $\mathrm{t}, J=7.0,1 \mathrm{H}, \operatorname{ArCH}), 7.52(\mathrm{t}, J=7.0,2 \mathrm{H}$, ArCH), 5.26 (brs, 1H, C=CHH), 5.09 (s, 1H, C=CHH), 3.74 (t, $J=7.0,2 H, C_{2}$ ), 1.92 (s, $3 \mathrm{H}, \mathrm{CH}_{3}$ ), 1.69-1.59 (quin. $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), 1.36-1.24 (sxt., $J=7.0,2 \mathrm{H}, \mathrm{CH}_{2}$ ), $0.90\left(\mathrm{t}, J=7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 172.7(\mathbf{s}, \mathbf{C}=\mathrm{O}), 141.2(\mathbf{s}, \mathbf{C}-$ $\mathrm{SO}_{2}$-), 139.8 ( $\mathbf{s}, \mathbf{C}=\mathrm{CH}_{2}$ ), 134.0 (d, ArCH ), 129.3 ( $2 \mathrm{x} \mathrm{d}, \mathrm{ArCH}$ ), 128.5 ( $2 \times \mathrm{d}, \mathrm{ArCH}$ ), $119.5\left(\mathbf{t}, \mathrm{C}=\mathrm{CH}_{2}\right), 47.7\left(\mathbf{t}, \mathrm{CH}_{2}\right), 32.2\left(\mathbf{t}, \mathrm{CH}_{2}\right), 20.3\left(\mathbf{t}, \mathrm{CH}_{2}\right), 20.0\left(\mathbf{q}, \mathrm{ArCH}_{3}\right), 14.0(\mathbf{q}$,

## Experimental

$\left.\mathrm{CH}_{3}\right) . \operatorname{LRMS}(\mathrm{LSIMS}) m / z: 282\left(\mathrm{MH}^{+}=100 \%\right), 165(12), 154$ (91), 136 (100), 115 (20). HRMS (LSIMS-FAB ${ }^{\dagger}$ ) $m / z:\left(\mathrm{MH}^{+}\right)$calcd for $\mathrm{C}_{14} \mathrm{H}_{20} \mathrm{NO}_{3} \mathrm{~S} ; 282.1164$, found 282.1166.

## Tris-(2-pyridylmethyl)-amine ${ }^{162} 279$

To a three necked RB flask was added 2-picoloyl chloride HCl ( $38.97 \mathrm{~g}, 234 \mathrm{mmol}, 2.0$ eq.) and 2-picoloylamine ( $12.98 \mathrm{~g}, 12.37 \mathrm{~mL}, 117 \mathrm{mmol}, 1.0$ eq.), the reaction mixture became a turbid dark red solution and slightly exothermic. To the mixture was added sodium hydroxide ( $10 \mathrm{M}, 24 \mathrm{~g}, 60 \mathrm{~mL}$ water) at a rate of one drop per minute. The reaction was stirred magnetically for 2 hr at room temperature. The crude product was extracted with chloroform ( $3 \times 150 \mathrm{~mL}$ ), and the organic phase was dried over anhydrous sodium sulfate. The solvent was removed in-vacuo to furnish dark red oil $(35.71 \mathrm{~g})$. To the crude product was added hot diethyl ether, the resulting blood red solution was decanted leaving a black viscous oil residue. The solvent was removed invacuo to furnish a bright orange red crystalline solid ( 32.02 g ). Recrystallisation with hot diethyl ether and rapid cooling lead to beautiful golden crystals tris-(2-pyridylmethyl)amine 279 (12.68g, $71 \%$ ). IR (neat) $v_{\text {max }}$ : 2823, 1589, 1433, 1366, 1147 and $766 \mathrm{~cm}^{-1}$. ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right) 8.54(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArH}), 7.68-7.57(\mathrm{~m}, 6 \mathrm{H}, \mathrm{ArH}), 7.15(\mathrm{~m}, 3 \mathrm{H}$, $\mathrm{ArH}), 3.89\left(\mathrm{~s}, 6 \mathrm{H},\left(\mathrm{CH}_{3}\right)_{2}\right) .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ) 159.4 (3 x s, C-py), 149.1 (3 $x$ d, $\operatorname{ArCH}$ ), $136.4(3 \times \mathbf{d}, \mathrm{ArCH}), 123.0(3 \mathrm{x} \mathrm{d}, \mathrm{ArCH}), 122.0$ (3 x d, ArCH$), 60.1$ ( 3 x

Appendix $5 \quad{ }^{1}$ H NMR of naphthalene rearranged amide 280 g

## APPENDICES

Appendix $6 \quad{ }^{1}$ H NMR of $p$-methoxy cyclised products

## APPENDICES

Appendix $7 \quad{ }^{1} \mathbf{H}$ NMR of fluoro cyclised product(s) 355

## APPENDICES

Appendix $8 \quad{ }^{1}$ H NMR of $p$-cyano rearranged amide 280i

## APPENDICES

Appendix $9{ }^{1} \mathrm{H}$ NMR of $\boldsymbol{p}$-cyano cyclised products $\mathbf{3 6 0 / 3 6 2}$

## APPENDICES

Appendix $10{ }^{1} \mathrm{H}$ NMR of $p$-nitro cyclised products $361 / 363$ or 366

## APPENDICES

Appendix $11{ }^{1} \mathrm{H}$ NMR of $\boldsymbol{p}$-TFM rearranged amide 280k

## APPENDICES

Appendix $12{ }^{1} \mathrm{H}$ NMR of bis-TFM rearranged amide 2801

## APPENDICES

Appendix $13{ }^{1} \mathrm{H}$ NMR of $N$-pentyl cyclised product 369c

## APPENDICES

Appendix $14{ }^{1} \mathrm{H}$ NMR of the $N$-propyl cyclised and reduced 375 b product

[^0]:    ${ }^{\text {a }}$ Significant amounts of uncharacterised by-product.

[^1]:    ${ }^{\mathbf{a}}$ Ratios for cyclisation of parent 278a in parenthesis for comparison
    Table 5 Effects of varying conditions on product distribution for 278e. As with the substituted phenyl precursor 278a a selection of solvents were used to determine the effects on product distribution and conversion. As before the reaction in toluene and DCM were the cleanest with those in THF and $\mathrm{H}_{2} \mathrm{O}$ producing other uncharacterised by-products. In addition, the reversal of selectivity moving from toluene to DCM (Entry II and III, Table 5) reflects the same trend as for the parent structure 278a (Entry IV and V, Table 3, page 100). The reason for the selectivity would most likely be due to a competition between cyclisation and rearrangement from the amidyl radical intermediate 335. In the case of a poor hydrogen donor, the reaction is pushed towards cyclisation. However, in the case of polar solvents such as DCM, the reaction is pushed towards rearrangement; this is because the amidyl radical intermediate can be quenched more readily from a better hydrogen donor.
